Apache Hive features in

Major changes to Apache Hive 2.x improve Apache Hive 3.x transactions and security. Knowing the major differences between these versions is critical for SQL users, including those who use Apache Spark and Apache Impala.

Hive is a data warehouse system for summarizing, querying, and analyzing huge, disparate data sets.

ACID transaction processing

Hive 3 tables are ACID (Atomicity, Consistency, Isolation, and Durability)-compliant. Hive 3 write and read operations improve the performance of transactional tables. Atomic operations include simple writes and inserts, writes to multiple partitions, and multiple inserts in a single SELECT statement. A read operation is not affected by changes that occur during the operation. You can insert or delete data, and it remains consistent throughout software and hardware crashes. Creation and maintenance of Hive tables is simplified because there is no longer any need to bucket tables.

Materialized views

Because multiple queries frequently need the same intermediate roll up or joined table, you can avoid costly, repetitious query portion sharing, by precomputing and caching intermediate tables into views.

Query results cache

Hive filters and caches similar or identical queries. Hive does not recompute the data that has not changed. Caching repetitive queries can reduce the load substantially when hundreds or thousands of users of BI tools and web services query Hive.

Scheduled Queries

Using SQL statements, you can schedule Hive queries to run on a recurring basis, monitor query progress, temporarily ignore a query schedule, and limit the number running in parallel. You can use scheduled queries to start compaction and periodically rebuild materialized views, for example.

Security improvements

Apache Ranger secures Hive data by default. To meet demands for concurrency improvements, ACID support, render security, and other features, Hive tightly controls the location of the warehouse on a file system, or object store, and memory resources.

With Apache Ranger and Apache Hive ACID support, your organization will be ready to support and implement GDPR (General Data Protection Regulation).

Connection Pooling

Hive supports HikariCP JDBC connection pooling.

Unsupported features

does not support the following features that were available in HDP and CDH platforms:

- Multiple insert overwrite queries that read data from a source table.
- CREATE TABLE that specifies a managed table location

Do not use the LOCATION clause to create a managed table. Hive assigns a default location in the warehouse to managed tables.

- **CREATE INDEX**

Hive builds and stores indexes in ORC or Parquet within the main table, instead of a different table, automatically. Set `hive.optimize.index.filter` to enable use (not recommended--use materialized views instead). Existing indexes are preserved and migrated in Parquet or ORC to during upgrade.

Spark integration with Hive

You need to know a little about Hive Warehouse Connector (HWC) and how to find more information because to access Hive from Spark, you need to use HWC implicitly or explicitly.

You can use the Hive Warehouse Connector (HWC) to access Hive managed tables from Spark. HWC is specifically designed to access managed ACID v2 Hive tables, and supports writing to tables in Parquet, ORC, Avro, or Textfile formats. HWC is a Spark library/plugin that is launched with the Spark app.

You do not need HWC to read from or write to Hive external tables. Spark uses native Spark to access external tables.

Use the Spark Direct Reader and HWC for ETL jobs. For other jobs, consider using Apache Ranger and the `HiveWarehouseConnector` library to provide row and column, fine-grained access to the data.

HWC supports `spark-submit` and `pyspark`. The `spark thrift` server is not supported.

Hive on Tez introduction

The Cloudera service provides an Apache Hive SQL database that Apache Tez executes.

The Hive on Tez service provides a SQL-based data warehouse system based on Apache Hive 3.x. The enhancements in Hive 3.x over previous versions can improve SQL query performance, security, and auditing capabilities. The Hive metastore (HMS) is a separate service, not part of Hive, not even necessarily on the same cluster. HMS stores the metadata on the backend for Hive, Impala, Spark, and other components.

Apache Tez is the Hive execution engine for the Hive on Tez service, which includes `HiveServer (HS2)` in Cloudera Manager. MapReduce is not supported. In a Cloudera cluster, if a legacy script or application specifies MapReduce for execution, an exception occurs. Most user-defined functions (UDFs) require no change to run on Tez instead of MapReduce.

With expressions of directed acyclic graphs (DAGs) and data transfer primitives, execution of Hive queries on Tez instead of MapReduce improves query performance. In Cloudera, Tez is usually used only by Hive, and launches and manages Tez AM automatically when Hive on Tez starts. SQL queries you submit to Hive are executed as follows:

- Hive compiles the query.
- Tez executes the query.
- Resources are allocated for applications across the cluster.
- Hive updates the data in the data source and returns query results.

Hive unsupported interfaces and features in on cloud

You need to understand the interfaces that are not supported in Cloudera.

The following interfaces are not supported:

- Hcat CLI (however, HCatalog is supported)

- Hive CLI (replaced by Beeline)
 - Hive View UI feature in Ambari
 - Renaming Hive databases
 - Multiple insert overwrite queries that read data from a source table.
 - MapReduce execution engine (replaced by LLAP)
 - Pig
 - Spark execution engine
 - Spark thrift server
- Spark and Hive tables interoperate using the Hive Warehouse Connector.
- SQL Standard Authorization
 - Tez View UI feature in Ambari
 - WebHCat

You can use Hue in lieu of Hive View.

Hive-Kudu integration

Cloudera does not support the integration of HiveServer (HS2) with Kudu tables. You cannot run queries against Kudu tables from HS2.

Unsupported Features

Cloudera does not support the following features that were available in HDP and CDH platforms:

- CREATE TABLE that specifies a managed table location

Do not use the LOCATION clause to create a managed table. Hive assigns a default location in the warehouse to managed tables. That default location is configured in Hive using the `hive.metastore.warehouse.dir` configuration property, but can be overridden for the database by setting the `CREATE DATABASE MANAGEDLOCATION` parameter.

- CREATE INDEX and related index commands were removed in Hive 3, and consequently are not supported in Cloudera.

In Cloudera, you use the Hive 3 default ORC columnar file formats to achieve the performance benefits of indexing. Materialized Views with automatic query rewriting also improves performance. Indexes migrated to Cloudera are preserved but render any Hive tables with an undroppable index. To drop the index, google the Known Issue for CDPD-23041.

- Hive metastore (HMS) high availability (HA) load balancing in CDH

You need to set up HMS HA as described in the documentation.

- Local or Embedded Hive metastore server

Cloudera does not support the use of a local or embedded Hive metastore setup.

Unsupported Connector Use

Cloudera does not support the Sqoop exports using the Hadoop jar command (the Java API) that Teradata documents. For more information, see [Migrating data using Sqoop](#).

Apache Hive 3 in architectural overview

Understanding Apache Hive 3 major design features, such as default ACID transaction processing, can help you use Hive to address the growing needs of enterprise data warehouse systems.

Data storage and access control

One of the major architectural changes to support Hive 3 design gives Hive much more control over metadata memory resources and the file system, or object store. The following architectural changes from Hive 2 to Hive 3 provide improved security:

- Tightly controlled file system and computer memory resources, replacing flexible boundaries: Definitive boundaries increase predictability. Greater file system control improves security.
- Optimized workloads in shared files and containers

Hive 3 is optimized for object stores in the following ways:

- Hive uses ACID to determine which files to read rather than relying on the storage system.
- In Hive 3, file movement is reduced from that in Hive 2.
- Hive caches metadata and data aggressively to reduce file system operations

The major authorization model for Hive is Ranger. Hive enforces access controls specified in Ranger. This model offers stronger security than other security schemes and more flexibility in managing policies.

This model permits only Hive to access the Hive warehouse.

Transaction processing

You can deploy new Hive application types by taking advantage of the following transaction processing characteristics:

- Mature versions of ACID transaction processing:

ACID tables are the default table type.

ACID enabled by default causes no performance or operational overload.

- Simplified application development, operations with strong transactional guarantees, and simple semantics for SQL commands

You do not need to bucket ACID tables.

- Materialized view rewrites
- Automatic query cache
- Advanced optimizations

Hive client changes

You can use the thin client Beeline for querying Hive from a client. You can run Hive administrative commands from the client. Beeline uses a JDBC connection to Hive to run commands. Hive parses, compiles, and runs operations. Beeline supports many of the command-line options that Hive CLI supported. Beeline does not support `hive -e set key=value` to configure the Hive Metastore.

You enter supported Hive CLI commands by invoking Beeline using the `hive` keyword, command option, and command. For example, `hive -e set`. Using Beeline instead of the thick client Hive CLI, which is no longer supported, has several advantages, including low overhead. Beeline does not use the entire Hive code base. A small number of daemons required to run queries simplifies monitoring and debugging.

Hive enforces allowlist and denylist settings that you can change using SET commands. Using the denylist, you can restrict memory configuration changes to prevent instability. Different Hive instances with different allowlists and denylists to establish different levels of stability.

Apache Hive Metastore sharing

Hive, Impala, and other components can share a remote Hive metastore.

Query execution of batch and interactive workloads

You can connect to Hive using a JDBC command-line tool, such as Beeline, or using an JDBC/ODBC driver with a BI tool, such as Tableau. You configure the settings file for each instance to perform either batch or interactive processing.

Apache Hive content roadmap

The content roadmap provides links to the available content resources for Apache Hive.

Table 1: Apache Hive Content roadmap

Task	Resources	Source	Description
Understanding	Presentations and Papers about Hive	Apache wiki	Contains meeting notes, presentations, and whitepapers from the Apache community.
Getting Started	Hive Tutorial	Apache wiki	Provides a basic overview of Apache Hive and contains some examples on working with tables, loading data, and querying and inserting data.
Developing	Materialized Views	Apache wiki	Covers accelerating query processing in Cloudera Data Warehouse by pre-computing summaries using materialized views.
	JdbcStorageHandler	Apache wiki	Describes how to read from a JDBC data source in Hive.
	Hive transactions	Apache wiki	Describes ACID operations in Hive.
	Hive Streaming API	Apache wiki	Explains how to use an API for pumping data continuously into Hive using clients such as NiFi and Flume.
	Hive Operators and Functions	Apache wiki	Describes the Language Manual UDF.
	Beeline: HiveServer2 Client	Apache wiki	Describes how to use the Beeline client.
