# **Release Information**

Version: Cloudera Altus Director 2.6.x

Date: October 31, 2018

# **Table of Contents**

Introduction	10
Cloudera Director Features	10
Displaying Cloudera Director Documentation	
Cloudera Director Interfaces	
Web User Interface	
Command-line interface	
API	
Stand-alone Client	14
Cloudera Director Interface Usage	15
Cloudera Director Release Notes	16
New Features and Changes in Cloudera Director	16
New Features and Changes in Cloudera Director 2	16
New Features and Changes in Cloudera Director 1	19
Known Issues and Workarounds in Cloudera Director	20
Tag on creation not available for AWS China and GovCloud	20
Failure to attach volumes when AMI volumes are present	20
Added instance groups are not configured based on their instance type	20
Maximum length of environment name is misleading	20
AWS rate limiting due to large number of EBS volumes	21
Cloudera Director cannot deploy Cloudera Navigator Key Trustee Server	21
Resize script cannot resize XFS partitions	21
Cloudera Director does not set up external databases for Sqoop2	21
Metrics not displayed for clusters deployed in Cloudera Manager 5.4 and earlier clusters	
Changes to Cloudera Manager username and password must also be made in Cloudera Director	21
Cloudera Director may use AWS credentials from instance of Cloudera Director server	
Root partition resize fails on CentOS 6.5 (HVM)	
When using RDS and MySQL, Hive Metastore canary may fail in Cloudera Manager	
Issues Fixed in Cloudera Director	
Issues Fixed in Cloudera Director 2.6.1	
Issues Fixed in Cloudera Director 2.6.0	
Issues Fixed in Cloudera Director 2.5.1	
Issues Fixed in Cloudera Director 2.5.0	
Issues Fixed in Cloudera Director 2.4.1	
Issues Fixed in Cloudera Director 2.4.0	
Issues Fixed in Cloudera Director 2.3.0	32
Issues Fixed in Clauders Director 2.2.0	20

Issues Fixed in Cloudera Director 2.1.1	37
Issues Fixed in Cloudera Director 2.1.0	38
Issues Fixed in Cloudera Director 2.0.0	39
Issues Fixed in Cloudera Director 1.5.2	39
Issues Fixed in Cloudera Director 1.5.1	40
Issues Fixed in Cloudera Director 1.5.0	40
Issues Fixed in Cloudera Director 1.1.3	40
Issues Fixed in Cloudera Director 1.1.2	41
Issues Fixed in Cloudera Director 1.1.1	41
Requirements and Supported Versions	43
Cloud Providers	43
Cloudera Director Service Provider Interface (SPI)	43
Supported Software and Distributions	
Resource Requirements	
Supported Cloudera Manager and CDH Versions	
Networking and Security Requirements	
Supported Browsers	
Getting Started with Cloudera Director	
Getting Started on Amazon Web Services (AWS)	
Setting up the AWS Environment	47
Launching an EC2 Instance for Cloudera Director	
Installing Cloudera Director Server and Client on the EC2 Instance	
Configuring a SOCKS Proxy for Amazon EC2	
Deploying Cloudera Manager and CDH on AWS	
Pausing a Cluster in AWS	
Cleaning Up Your AWS Deployment	
Getting Started on Google Cloud Platform	
Creating a Google Cloud Platform Project	
Configuring Tools for Your Google Cloud Platform Account	
Creating a Google Compute Engine VM Instance	
Installing Cloudera Director Server and Client on Google Compute Engine	
Configuring a SOCKS Proxy for Google Compute Engine	
Deploying Cloudera Manager and CDH on Google Compute Engine	
Cleaning Up Your Google Cloud Platform Deployment	
Getting Started on Microsoft Azure	
Obtaining Credentials for Cloudera Director	
Setting up Azure Resources	
Setting Up Dynamic DNS on Azure	
Setting Up MySQL or PostgreSQL	
Setting Up a Virtual Machine for Cloudera Director Server	90

Installing Cloudera Director Server and Client on Azure	90
Configuring a SOCKS Proxy for Microsoft Azure	92
Allowing Access to VM Images	93
Creating a Cluster	93
Adding New VM Images, Custom VM Images, Regions, and Instances	100
Important Notes About Cloudera Director and Azure	101
Usage-Based Billing	106
Prerequisites	106
How Usage-Based Billing Works	106
Deploying Cloudera Manager and CDH with Usage-Based Billing	
Enabling Usage-Based Billing with the Cloudera Director Server web UI	
Enabling Usage-Based Billing with bootstrap-remote	
Managing Billing IDs with an Existing Deployment	108
Troubleshooting Network Connectivity for Usage-Based Billing	
Cloudera Director Usage Bundles	
Metadata Section	
Cloudera Manager Block	
Cloudera Director Block	110
Usage Logging	110
Using Cloud Provider Regions	112
Running Cloudera Director and Cloudera Manager in Different Regions or Clouds	112
Using a New AWS Region in Cloudera Director	113
Entering the Region Code	113
Region Endpoints	113
Other Considerations	114
Configuring Storage for Cloudera Director	115
Using MySQL for Cloudera Director Server	
Installing the MySQL Server	
Configuring and Starting the MySQL Server	
Installing the MySQL JDBC Driver	
Creating a Database for Cloudera Director Server	118
Configuring Cloudera Director Server to use the MySQL Database	119
Migrating Cloudera Director Server from H2 to MySQL	119
Step 1: Preparation of databases	119
Step 2: Export data from H2 database	120
Step 3: Prepare MySQL database for data import	
Step 4: Import data to MySQL	128
Using MariaDB for Cloudera Director Server	128
Installing the MariaDB Server	128

Configuring and Starting the MariaDB Server	129
Installing the MariaDB JDBC Driver	130
Creating a Database for Cloudera Director Server	131
Configuring Cloudera Director Server to use the MariaDB Database	131
Cloudera Director Database Encryption	132
Cipher Configuration	132
Starting with Encryption	133
Changing Encryption	134
Configuring Storage for Cloudera Manager and CDH	136
Using an External Database for Cloudera Manager and CDH	136
Defining External Database Servers	
Defining External Databases	142

Appendix: Apache License, Version 2.0	240

# Introduction

Cloudera Director enables reliable self-service for using CDH and Cloudera Enterprise Data Hub in the cloud.

Cloudera Director provides a single-pane-of-glass administration experience for central IT to reduce costs and deliver agility, and for end-users to easily provision and scale clusters. Advanced users can interact with Cloudera Director programmatically through the REST API or the CLI to maximize time-to-value for an enterprise data hub in cloud environments.

Cloudera Director is designed for both long running and transient clusters. With long running clusters, you deploy one or more clusters that you can scale up or down to adjust to demand. With transient clusters, you can launch a cluster, schedule any jobs, and shut the cluster down after the jobs complete.

Running Cloudera in the cloud supports:

- Faster procurement—Deploying servers in the cloud is faster than completing a lengthy hardware acquisition process.
- Easier scaling—To meet changes in cluster demand, it is easier to add and remove new hosts in the cloud than in a bare metal environment.
- · Infrastructure migration—Many organizations have already moved to a cloud architecture, while others are in the process of moving.

For more information about Cloudera Enterprise in the cloud, see the Cloud documentation page.

# Cloudera Director Features

Cloudera Director provides a rich set of features for launching and managing clusters in cloud environments. The following table describes the benefits of using Cloudera Director.

Benefit	Features
Simplified cluster lifecycle management	<ul> <li>Simple user interface:</li> <li>Self-Service spin up and tear down</li> <li>Scaling of clusters for spiky workloads</li> <li>Simple cloning of clusters</li> <li>Cloud blueprints for repeatable deployments</li> </ul>
Elimination of lock-in	<ul> <li>Flexible, open platform:</li> <li>100% open source Hadoop distribution</li> <li>Native support for hybrid deployments</li> <li>Third-party software deployment in the same workflow</li> <li>Support for custom, workload-specific deployments</li> </ul>
Accelerated time to value	<ul> <li>Enterprise-ready security and administration:</li> <li>Support for complex cluster topologies</li> <li>Minimum size cluster when capacity constrained</li> <li>Management tooling</li> <li>Compliance-ready security and governance</li> <li>Backup and disaster recovery with an optimized cloud storage connector</li> </ul>
Reduced support costs	Monitoring and metering tools:

Benefit	Features	
	Multi-cluster health dashboard	
	Instance tracking for account billing	

# Displaying Cloudera Director Documentation

To display Cloudera Director documentation for any page in the server web UI, click the question mark icon in the upper-right corner at the top of the page:

# cloudera director

The latest help files are hosted on the Cloudera web site, but help files are also embedded in the product for users who do not have Internet access. By default, the help files displayed when you click the question mark icon are those hosted on the Cloudera web site because these include the latest updates. You can configure Cloudera Director to open either the latest help from the Cloudera web site or locally installed help by toggling the value of lp.webapp.documentationType to ONLINE or EMBEDDED in the server application.properties configuration file at /etc/cloudera-director-server/.

If you edit the server application.properties file while Cloudera Director server is running, you must restart the server in order for your changes to take effect:

\$ sudo service cloudera-director-server restart

# Cloudera Director Interfaces

Cloudera Director provides different user interfaces for centralized deployment, configuration, and administration of Cloudera Manager and CDH clusters in the cloud. After you complete the Cloudera Director installation, you can use any interface to deploy Cloudera Manager and CDH clusters in the cloud. To manage the CDH deployment, use the interface that is appropriate for the complexity of the configuration or administrative tasks that you need to perform.

Cloudera Director provides the following user interfaces:

- Web User Interface (Web UI) The web UI is a graphical interface to deploy and manage clusters in the cloud. You can use the web UI to monitor the clusters and access the cluster activity logs.
- Command-Line Interface (CLI) The command-line interface uses a configuration file to define the settings for a cluster. The configuration file allows you to deploy clusters with custom settings and without operator intervention.
- API You can use the Cloudera Director API to programmatically control the lifecycle of your clusters. Cloudera Director provides SDKs for the Python and Java programming languages.
- Standalone Client If you install the client without installing the server, you can use the client as a standalone application to deploy and manage clusters. The standalone client provides a command-line interface for deploying simple clusters that you can manage using the local commands. Use the standalone client to deploy CDH clusters for testing or development, not for production.

#### Web User Interface

After you install the Cloudera Director server, you can use a browser to access the Cloudera Director web UI.

The web UI has a dashboard that shows the available environments and displays information about the Cloudera Manager deployments and the clusters in the deployment. Use the setup wizard in the web UI to easily and quickly deploy clusters in the cloud. You can also use the web UI to define environments, deployments, and clusters, add nodes to clusters, or clone clusters.

When you use the web UI to deploy a cluster, Cloudera Director saves the state of the cluster in the Cloudera Director database. The database can store deployment information about multiple environments, deployments, and clusters

that are deployed and managed by Cloudera Director. The deployment information in the database allows Cloudera Director to create additional clusters in the managed deployments.

By default, Cloudera Director saves deployment information in an H2 database, but the H2 database is only supported for proof-of-concept clusters or for testing. Configure Cloudera Director to use an externally managed MySQL or MariaDB database for production clusters. Specify an external database in the application.properties file in the server host. For more information, see Configuring Storage for Cloudera Director on page 115.

If you use the web UI to deploy Cloudera Manager and CDH, you can use the web UI or API to manage the Cloudera Manager deployment, terminate clusters, or deploy additional clusters. You can use the command-line interface to deploy more clusters or to terminate clusters. You can also use the web UI to manage clusters if you use the command-line interface or API to deploy them.

You can use the web UI to perform any configuration or administrative task on a Cloudera Manager deployment. However, when you perform a complex or customized deployment or configuration, you might find it easier and more reliable to use the command-line interface with a configuration file or to use the API.

#### Command-line interface

To use the Cloudera Director command-line interface, you must install the Cloudera Director client in addition to the server. You can install the Cloudera Director client separately from the server. You can install the client in multiple locations, with all clients communicating with the same Cloudera Director server in the cloud.

When you run a command, the client connects to the server to complete the operation. To connect to the server, the client requires the host and user account information for the Cloudera Director server.

When you use the command-line interface to deploy a cluster, the state of the cluster is saved in the Cloudera Director database. The database can store deployment information about multiple environments, deployments, and clusters that are deployed and managed by Cloudera Director. The deployment information in the database allows Cloudera Director to create additional clusters within the managed deployments.

If you use the command-line interface to deploy a cluster, you can use the web UI or the API to manage the cluster.

#### **Application Properties File**

When you install the Cloudera Director client, the installation creates a configuration file named application.properties. The properties file includes configuration properties such as the Cloudera Director server host, port number, and user account. You can modify the settings in the application.properties file based on your operational requirements.

By default, the command-line interface reads the settings in the application.properties file on the client host to determine the parameters of a command. When you run a command, you can override properties in the application.properties file by passing the properties directly to the command. For example, you can pass the hostname and port number for the Cloudera Director server. If you do not include these properties in the command, the command reads the properties from the application.properties file.

#### Cluster Configuration File

A template is a common and useful way to define the configuration and infrastructure of a cloud deployment. Cloudera Director uses a configuration file as a template for cluster deployments in the cloud. You can use the configuration file to define your cluster deployment across different cloud environments.

The Cloudera Director command-line interface uses a configuration file to determine the deployment configuration for a cluster. When you use the command-line interface to deploy a cluster, you must provide the configuration file name. The command reads the file you specify and deploys a cluster configured with the settings defined in the configuration file.

You can create multiple configuration files to deploy clusters with different settings, or you can reuse a configuration file to deploy multiple clusters with the same settings. Cloudera provides sample configuration files that you can use as templates to start a configuration file for your cluster deployment. You can find the sample configuration files on the Cloudera Director scripts GitHub page.

#### Commands

The command-line interface includes the following commands:

Command	Description	
bootstrap-remote	Creates an environment, deployment, and cluster on a remote server based on the settings in a configuration file. The configuration file name must have a .conf extension. The bootstrap-remote command reads the configuration file and creates a cluster with the configuration settings defined in the file. As with Director UI installations,	
	bootstrap-remote speeds up the bootstrap process by configuring Cloudera Manager and the CDH cluster in parallel.	
	To ensure that the command connects to the Cloudera Director server correctly, you can pass server host and user account properties to the command. The bootstrap-remote command uses the values you pass to connect to the server instead of the values in the application.properties file. For example, you can pass the following properties:	
	• lp.remote.hostAndPort=host[:port]	
	Hostname and port number of the Cloudera Director server. The default value in the application.properties file is set to localhost: 7189	
	• lp.remote.username= <cloudera director="" server="" username=""></cloudera>	
	Username to use to log in to the Cloudera Director server.	
	• lp.remote.password= <cloudera director="" password="" server=""></cloudera>	
	Password for the Cloudera Director server user account.	
terminate-remote	Terminates a cluster and deployment on a remote server.	
	As in the bootstrap-remote command, you can pass the hostname and port number to connect to the Cloudera Director server and the username and password to log in to Cloudera Director.	
validate	Validates the configuration file of an environment, deployment, or cluster. For clusters, it validates the correctness of the role and service types, but not the configuration keys, values, or semantics of the role placement	
	You can set the lp.validate.verbose property to true to output an HTML representation of the configuration.	

# API

Cloudera Director has an API that provides access to all Cloudera Director features. The Cloudera Director API is a REST API that uses JSON as the data interchange format.

Use the API to access Cloudera Director from a script or to integrate Cloudera Director features with an application. The API includes SDKs to help you integrate Cloudera Director into Python or Java applications. You can use the API to deploy Cloudera Manager and CDH clusters on any cloud environment supported by Cloudera Director. You can find information about the Cloudera Director Java and Python APIs on the Cloudera Director SDK GitHub page.

The API includes a console to assist the development process. You can use the API console during development to interactively configure settings or perform ad hoc operations on the cluster in the cloud. You can also use it to explore Cloudera Director features and to test and troubleshoot clusters. You can access the API console for your deployment at http://director-server-hostname:7189/api-console.

#### Stand-alone Client

You can install the Cloudera Director client without installing the server. If you install the Cloudera Director client only, you can run local client commands to deploy and manage simple clusters.

When you install the client, the installation creates a configuration file named application.properties locally. The client uses the settings in the local application.properties file to determine the parameters of the command. When you run a command, you can override properties in the local application properties file by passing the properties directly to the command.

The stand-alone client also uses a configuration file to determine the deployment configuration for a cluster. You can define the configuration settings for a cluster setup in a configuration file and use the local bootstrap command to deploy clusters based on the settings in the configuration file. You can reuse a configuration file to deploy multiple clusters with the same configuration. Cloudera provides sample configuration files that you can use as templates to start a configuration file for your cluster deployment. You can find the sample configuration files on the Cloudera Director scripts GitHub page.

When you use a local command to deploy a cluster, the state of the environment and cluster is saved in a local H2 database. The database stores information only for a single environment and deployment and allows only a limited set of operations to be performed on the deployed cluster. All local commands operate on the cluster deployment that is described in the local database.

If you use the local bootstrap command to deploy a cluster, you cannot use the web UI or the API to manage the cluster. You must manage the cluster using the local client commands. Cloudera recommends that you use the local client commands to deploy and manage clusters for demonstrations and development, not for production.

You can use the following local commands to deploy and manage a simple cluster:

Command	Description		
bootstrap	Creates an environment, deployment, and cluster based on the settings defined in a configuration file. The configuration file name must have a .conf extension.		
	The bootstrap command is comparatively slower than bootstrap-remote command. This is because, while bootstrap-remote configures Cloudera Manager and the CDH cluster in parallel, bootstrap configures a CDH cluster only after it configures Cloudera Manager.		
	Note: If you use the local bootstrap command to deploy a cluster, you cannot use the web UI or the API to update or manage the cluster.		
status	Reports the status of an environment, deployment, and cluster.		
terminate	Terminates a cluster or deployment. Requires a configuration file.  You can set the lp.remote.terminate.assumeYes property. This property determines if the user must explicitly confirm termination (false) or if confirmation is assumed (true). The default value is false. Setting this property to true will cause termination to proceed even if diagnostic data collection has failed. For more information, see <a href="Diagnostic Data Collection">Diagnostic Data Collection</a> on page 195		
update	Updates an environment, deployment, and cluster. Requires a configuration file.		
validate	Validates the configuration file of an environment, deployment, or cluster. For clusters, it validates the correctness of the role and service types, but not the configuration keys, values, or semantics of the role placement  You can set the lp.validate.verbose property to true to output an HTML representation of the configuration.		

# Cloudera Director Interface Usage

The following table shows the tasks you can perform in the different Director interfaces:

Task	Web UI	Command-line Interface	АРІ	Stand-alone Client
Deploy simple clusters				
Deploy complex clusters with Kerberos or high availability				
Deploy in production				
View dashboard of cluster deployment				
Manage multiple clusters				
Add nodes to clusters				
Remove nodes from clusters				
Clone clusters				
Update Cloudera Manager password				
Terminate clusters				

# Cloudera Director Release Notes

These release notes provide information on new features and known issues and limitations for Cloudera Director.

For information about supported operating systems, and other requirements for using Cloudera Director, see Requirements and Supported Versions.

# New Features and Changes in Cloudera Director

# New Features and Changes in Cloudera Director 2

#### What's New in Cloudera Director 2.6.1

A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 2.6.1</u> for details.

#### What's New in Cloudera Director 2.6.0

- Expanded support for TLS:
  - Automatic TLS for Cloudera Manager and CDH: Cloudera Director now provides the ability to automatically configure Cloudera Manager 5.13 or later and CDH 5.13 or later with TLS using a bespoke certificate authority based on the Cloudera Manager instance. See Automatic TLS (Auto-TLS).
  - TLS Support for Cloudera Manager: Cloudera Director is now able to communicate with Cloudera Manager 5.13 or later after it has been configured manually to communicate over TLS. See Manual TLS.
  - TLS Support for Cloudera Director clients: The Java and Python client libraries and the Cloudera Director client are now able to communicate with the Cloudera Director server after the server has been configured to communicate over TLS. See TLS for Cloudera Director Itself.
- SSH Host Key Support: Cloudera Director can now retrieve SSH host keys from instances it allocates to provide extra security. See **SSH** Host Key Retrieval and Verification.
- Support for including <u>Cloudera Data Science Workbench</u> when installing CDH on AWS with a Cloudera Director configuration file.
- Starting with Cloudera Manager 5.13, Cloudera Director is able to delete Kerberos principals automatically created for a cluster when the cluster is terminated.
- AWS EBS volumes with provisioned IOPS are now supported.
- An instance template now supports specification of a rack ID for instances created from it. The rack ID can be used by Cloudera Manager and CDH to guide data distribution and increase durability.
- New features and changes with Microsoft Azure:
  - Simplified Azure Environment and instance template configurations. Configurations from previous releases of Cloudera Director will continue to be supported.
  - Support for Azure Managed Disks. Azure Managed Disks are an improvement over Azure Storage Accounts. They simplify storage, provide better reliability for availability sets, and improve scalability. For more information on Managed Disks, see Azure Managed Disks Overview.
  - The instance prefix requirements have been relaxed to support prefixes of one and two characters.
  - Virtual machines can now be provisioned without an Availability Set.
  - Support for new disk sizes:
    - P/S40 (2048 GB)
    - P/S50 (4095 GB)
  - Some web UI menu items have been moved from the Advanced section to the Basic section.
  - Referencing Azure Marketplace Images inline in the Image field is now supported using this format: /publisher/<publisher>/offer/<offer>/sku/<sku>/version/<version>.

- Deploying clusters with custom images is now supported when using Azure Managed Disks. See Deploying Clusters with Custom Images.
- A beta of version 2 of the Cloudera Director plugin SPI is available, and the plugins that ship with Cloudera Director are updated to use it.
- A number of issues have been fixed. See Issues Fixed in Cloudera Director 2.6.0 for details.

#### What's New in Cloudera Director 2.5.1

• A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 2.5.1</u> for details.

#### What's New in Cloudera Director 2.5.0

- Automatic repair: Cloudera Director can now automatically repair instances that get terminated unexpectedly for clusters that have auto-repair enabled.
- Significant improvement in resilience to unexpected instance terminations during bootstrap and grow operations. This improves support for AWS spot instances, as well as resilience of clusters using on-demand instances.
- Cloudera Director can now configure and create external accounts in Cloudera Manager that include cloud provider login credentials in order to manage the use of additional cloud provider functionality, including object stores, such as Amazon S3 in AWS.
- Cloudera Director now supports S3Guard, which guarantees a consistent view of data stored in Amazon S3.
- Cloudera Director can now recognize changes made directly from the cloud provider console to provisioned instances such as instance type and AMI.
- Cluster details page in the web UI now shows cluster history, displaying the most recent updates, including instances added, removed, or replaced in the cluster.
- · Logging improvements, including additional information about service and role configuration errors returned by the Cloudera Manager API.
- A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 2.5.0</u> for details.

#### What's New in Cloudera Director 2.4.1

- Support for the following Microsoft Azure instance types:
  - Standard D12 v2
  - Standard D13 v2
  - Standard\_D14\_v2
  - Standard\_D15\_v2

Refer to the Cloudera Reference Architecture on Azure for supported configurations using these Storage Account

A number of issues have been fixed. See Issues Fixed in Cloudera Director 2.4.1 for details.

#### What's New in Cloudera Director 2.4.0

- Improved support for long-running clusters: Cloudera Director 2.4 will support upgrades, change of services, and configurations from Cloudera Manager 5.11.
- Support for Spark 2 and Kudu.
- Support for multiple bootstrap scripts. This feature allows you to combine functionality required during bootstrap while maintaining modularity. Using multiple scripts is beneficial when different parts of the customized bootstrap have different retry semantics, because retry upon failure is done only for failed scripts.
- Configurable AWS instance tag names and values.
- Support for passing of AWS user data to instances while they are being launched.
- Sample code using the Java SDK to grow, shrink and repair the cluster. See <u>Cloudera Director Java Client Samples</u>.
- For Azure clusters, support for Azure Data Lake Store via Cloudera Manager and CDH 5.11 deployments.
- Support for the following Microsoft Azure Clouds and Regions:
  - Azure Government: US GOV VIRGINIA
  - Azure Germany: Germany Central and Germany Northeast

- Added RHEL 6.8 to the default OS list for Azure.
- Improved error logging for Azure clusters.
- A number of issues have been fixed. See Issues Fixed in Cloudera Director 2.4.0 for details.

#### What's New in Cloudera Director 2.3.0

- Support for AWS Spot Blocks. Spot blocks can be used to ensure the duration of instances during bootstraps so that the bootstrap process is resilient to fluctuations in AWS Spot instance availability. For more information, see Specifying a Duration for Your Spot Instances in the Amazon AWS documentation.
- More control of cluster configuration with the introduction of instance-level and deployment-level post-creation scripts, in addition to existing cluster-level post-creation scripts.
- Updated look and feel of the Cloudera Director web user interface.
- Support for Cloudera Enterprise 5.10 out of the box.
- Support for RHEL 6.8 and RHEL 7.3 for Cloudera Director and CDH cluster instances.
- Support for the following Microsoft Azure instance types:
  - Standard DS15 v2
  - Standard GS4
  - Standard GS5

Refer to the Cloudera Reference Architecture on Azure for supported configurations using these Storage Account

- On Microsoft Azure, support for the CentOS 6.8 image published by Cloudera.
- A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 2.3.0</u> for details.

#### What's New in Cloudera Director 2.2.0

- Support for AWS EBS volumes. See <u>Using EBS Volumes for Cloudera Manager and CDH</u>.
- On-demand and automatically-upon-failure diagnostic data collection. See <u>Diagnostic Data Collection</u>.
- Improved readability and validation of input configuration files.
- Support for Cloudera Enterprise 5.9 out of the box.
- Support for the following Microsoft Azure Storage Account types. Refer to the Cloudera Reference Architecture on Azure for supported configurations using these Storage Account types:
  - Premium LRS
  - Standard LRS
- Support for Azure's P20 (512 GiB) disk type for Premium Storage Accounts. This is in addition to the already-supported P30 disk type. Refer to the <u>Cloudera Reference Architecture on Azure</u> for supported disk size configurations.
- On Microsoft Azure, support for the RHEL 7.2 image published by Red Hat in partnership with Microsoft and the CentOS 7.2 image published by Cloudera.
- A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 2.2.0</u> for details.

#### What's New in Cloudera Director 2.1.1

- Cloudera Director now includes support for the following Microsoft Azure instance types:
  - Standard DS12 v2
  - Standard\_DS13\_v2
  - Standard\_DS14\_v2
- On Microsoft Azure, Cloudera Director now supports the RHEL 6.7 image published by Red Hat in partnership with Microsoft.
- A number of issues have been fixed. See Issues Fixed in Cloudera Director 2.1.1 for details.

#### What's New in Cloudera Director 2.1.0

- Usage-based billing, where the cost of running a cluster is based on cluster usage, is supported. See <u>Usage-Based</u> Billing on page 106.
- Running CM and CDH clusters on Microsoft Azure is supported. See Getting Started on Microsoft Azure on page
- Deploying Cloudera Manager and CDH on a different cloud provider or region than Cloudera Director with a simple network setup is supported. See Running Cloudera Director and Cloudera Manager in Different Regions or Clouds on page 112.
- Cloudera Enterprise 5.7 is supported out of the box.
- A number of issues have been fixed. See Issues Fixed in Cloudera Director 2.1.0 for details.

#### What's New in Cloudera Director 2.0.0

- AWS Spot instances and Google Cloud Platform preemptible virtual machine instances are supported.
- Setup of clusters that are highly available and authenticated through Kerberos is automated.
- You can automate submission of jobs to clusters with dynamic creation and termination of clusters.
- You can run custom scripts after cluster setup and before cluster termination.
- The user interface is enhanced, with deeper insights into cluster health.
- Reliability of cluster modifications is increased, including rollback in some failure scenarios.
- RHEL 7.1 is supported.
- A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 2.0.0</u> for details.

# New Features and Changes in Cloudera Director 1

The following sections describe what's new and changed in each Cloudera Director 1 release.

#### What's New in Cloudera Director 1.5.2

- Cloudera Director now supports RHEL 6.7.
- A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 1.5.2</u> for details.

# What's New in Cloudera Director 1.5.1

A number of issues have been fixed. See Issues Fixed in Cloudera Director 1.5.1 on page 40 for details.

#### What's New in Cloudera Director 1.5.0

- Cloudera Director now supports multiple cloud providers through an open-source plugin interface, the Cloudera Director Service Provider Interface (Cloudera Director SPI).
- Google Cloud Platform is now supported through an open-source implementation of the Cloudera Director SPI, the Cloudera Director Google Plugin.
- Database servers set up by Cloudera Director can now be managed from the web UI.
- You can now specify custom scripts to be run after cluster creation. Example scripts for enabling HDFS high availability and Kerberos are available on the Cloudera GitHub site.
- The Cloudera Director database can now be encrypted. Encryption is enabled by default for new installations.
- Cluster and Cloudera Manager configurations can now be set through the web UI.
- A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 1.5.0</u> on page 40 for details.

#### What's New in Cloudera Director 1.1.3

- A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 1.1.3</u> on page 40 for details.
- The Cloudera Director disk preparation method now supports RHEL 6.6, which is supported by Cloudera Manager 5.4.
- Custom endpoints for AWS Identity and Access Management (IAM) are now supported.
- To ensure version compatibility between Cloudera Manager and CDH, Cloudera Director now defaults to installing the latest 5.3 version of Cloudera Manager and CDH, rather than installing the latest post-5.3 version.

#### What's New in Cloudera Director 1.1.2

• A number of issues have been fixed. See Issues Fixed in Cloudera Director 1.1.2 for details.

#### What's New in Cloudera Director 1.1.1

A number of issues have been fixed. See <u>Issues Fixed in Cloudera Director 1.1.1</u> for details.

# What's New in Cloudera Director 1.1.0

- Support for demand-based shrinking of clusters
- Integration with Amazon RDS to enable end-to-end setup of clusters as well as related databases
- · Native client bindings for Cloudera Director API in Java and Python
- Faster bootstrap of Cloudera Manager and clusters
- Improved User Interface of Cloudera Director server including display of health of clusters and ability to customize cluster setups
- Improvements to usability and documentation

# Known Issues and Workarounds in Cloudera Director

The following sections describe the current known issues in Cloudera Director.

# Tag on creation not available for AWS China and GovCloud

The AWS plugin in Cloudera Director 2.5 and higher now supports tagging instances on creation for reliability purposes. However, neither the AWS China region nor AWS GovCloud currently support this functionality. For more information about tagging on creation for AWS instances, see the AWS blog article Tag EC2 Instances & EBS Volumes on Creation.

Workaround: Use Cloudera Director 2.4 if you require tag-on-create functionality for these regions until the regions have been updated by AWS.

Cloudera Bug: DIR-6920

#### Failure to attach volumes when AMI volumes are present

When using an AMI that has volumes associated with it, Cloudera Director may fail to attach additional EBS or instance store volumes or may fail to attach the volumes associated with the AMI. This will happen if the device names for the AMI overlap with the device names that Cloudera Director uses to attach EBS and instance store volumes.

Workaround: Override the default device naming configurations in the AWS plugin. For more information about device naming, see Configuring Device Names for EBS Volumes and Instance Store Volumes.

Cloudera Bug: DIR-6757

#### Added instance groups are not configured based on their instance type

Newly added instance groups are not automatically configured. Roles on the new instances will be given the same configuration as existing roles even if the new instance uses a different instance type than the old instances.

Workaround: Update the role group in Cloudera Manager after the cluster update completes.

Cloudera Bug: DIR-5102

# Maximum length of environment name is misleading

Parsing of a Cloudera Director configuration file can produce errors indicating that the environment name and, sometimes additionally, the deployment name are too long, even though the names were not specified in the file. This is a consequence of Cloudera Director automatically generating those names, based on the cluster name, when they are not explicitly given in the file. When the cluster name is long, the automatically-generated names exceed the length limits.

Workaround: Provide explicit names for the environment and deployment in the configuration file. Examples:

environmentName: MyEnvironment deploymentName: MyDeployment

Cloudera Bug: DIR-6301

#### AWS rate limiting due to large number of EBS volumes

Standing up a cluster with a large number of EBS volumes might trigger rate limiting on EBS allocation requests. The effect can spread to other calls from Cloudera Director to AWS.

Workaround: No more than 10 EBS volumes should be attached at a time.

Cloudera Bug: DIR-4283

# Cloudera Director cannot deploy Cloudera Navigator Key Trustee Server

Cloudera Navigator Key Trustee Server cannot be one of the services deployed by Cloudera Director.

Workaround: Set up Cloudera Navigator Key Trustee Server via Cloudera Manager if using Cloudera Director 2.4 and above.

Cloudera Bug: DIR-1757

# Resize script cannot resize XFS partitions

Cloudera Director is unable to resize XFS partitions, which makes creating an instance that uses the XFS filesystem fail during bootstrap.

Workaround: Use an image with an ext filesystem such as ext2, ext3, or ext4.

Cloudera Bug: DIR-2716

#### Cloudera Director does not set up external databases for Sgoop2

Cloudera Director cannot set up external databases for Sqoop2.

Workaround: Set up databases for this service as described in Cloudera Manager and Managed Service Databases.

Cloudera Bug: DIR-1832

# Metrics not displayed for clusters deployed in Cloudera Manager 5.4 and earlier clusters

Clusters deployed in Cloudera Manager version 5.4 and lower might not have metrics displayed in the web UI if these clusters share the same name as previously deleted clusters.

Workaround: Use Cloudera Manager 5.5 and higher.

Cloudera Bug: DIR-2422

#### Changes to Cloudera Manager username and password must also be made in Cloudera Director

If the Cloudera Manager username and password are changed directly in Cloudera Manager, Cloudera Director can no longer add new instances or authenticate with Cloudera Manager. Username and password changes must be implemented in Cloudera Director as well. For more information on keeping Cloudera Director and Cloudera Manager in sync, see CDH Cluster Management Tasks.

Workaround: Use the Cloudera Director web UI to update the Cloudera Manager username and password.

#### Cloudera Director may use AWS credentials from instance of Cloudera Director server

Cloudera Director Server uses the AWS credentials from a configured Environment, as defined in a client configuration file or through the Cloudera Director web UI. If the Environment is not configured with credentials in Cloudera Director, the Cloudera Director server instead uses the AWS credentials that are configured on the instance on which the Cloudera Director server is running. When those credentials differ from the intended ones, EC2 instances may be allocated under unexpected accounts. Ensure that the Cloudera Director server instance is not configured with AWS credentials.

Severity: Medium

Workaround: Ensure that the Cloudera Director Environment has correct values for the keys. Alternatively, use IAM profiles for the Cloudera Director server instance.

Cloudera Bug: DIR-1040

# Root partition resize fails on CentOS 6.5 (HVM)

Cloudera Director cannot resize the root partition on Centos 6.5 HVM AMIs. This is caused by a bug in the AMIs. For more information, see the CentOS Bug Tracker.

Cloudera Bug: DIR-757

# When using RDS and MySQL, Hive Metastore canary may fail in Cloudera Manager

If you include Hive in your clusters and configure the Hive metastore to be installed on MySQL, Cloudera Manager may report, "The Hive Metastore canary failed to create a database." This is caused by a MySQL bug in MySQL 5.6.5 or higher that is exposed when used with the MySQL JDBC driver (used by Cloudera Director) version 5.1.19 or lower. For information on the MySQL bug, see the MySQL bug description.

Workaround: Depending on the driver version installed by Cloudera Director from your platform's software repositories, select an older MySQL version that does not have this bug.

Cloudera Bug: DIR-923

# Issues Fixed in Cloudera Director

The following sections describe fixed issues in each Cloudera Director release.

# Issues Fixed in Cloudera Director 2.6.1

#### Proxy settings do not work with the Cloudera Director CLI

The Cloudera Director command line client does not recognize proxy settings.

Cloudera Bug: DIR-7405

#### SSH heartbeat threads leaking

SSH heartbeat threads can be leaked if connectivity to the underlying instance fails.

Cloudera Bug: DIR-7675

#### Bootstrap of clusters for "All Services" or "Real Time Ingest" fails when using web UI

When using the Cloudera Director web UI to bootstrap a cluster, there are several choices for the set of services to install in the cluster. The selections All Services and Real Time Ingest include Kafka as a cluster service. The default parcel repositories for cluster services in Cloudera Director 2.6.0 include Kafka 3.0, but the Cloudera Director UI erroneously requests Kafka version 2 by default, causing bootstrap for clusters including Kafka to fail.

#### Update failure when replacing instances with reused private IP addresses

When Cloudera Director is used to replace bad or failed instances, the update can fail if the new host has the same private IP address as the host being replaced.

Cloudera Bug: DIR-7332

#### Solr servers treated as master roles by Cloudera Director for migrations

Starting in Director 2.5.0, the Solr server cluster role was treated as a master role and not available for automatic role migration. It should instead be treated as a worker role. This miscategorization resulted in Cloudera Director invoking the manual migration workflow when replacing instances with the Solr server role.

Workaround: Follow the manual migration workflow to transfer roles to the new instances.

Cloudera Bug: DIR-7329

#### NumberFormatException during cluster bootstrap

In Cloudera Director 2.6.0, near the end of cluster bootstrap or update, there may be a parsing error expressed as a NumberFormatException in the server or client log:

```
java.lang.NumberFormatException: null
   at java.lang.Long.parseLong(Long.java:552)
   at java.lang.Long.parseLong(Long.java:631)
con.claudera.laundped.bootstrap.cluster.AdjustClauderaVanagementServices.makeAdjustments(AdjustClauderaVanagementServices.java:155)
```

While the cluster is still usable after this error, the cluster may end up in an UPDATE\_FAILED state.

Workaround: Set the following configuration property in Cloudera Director's application.properties file. This workaround only works if you are not using the new auto-TLS feature of Cloudera Director 2.6.

```
lp.bootstrap.cluster.adjustcm.useAutoConfigure: true
```

Cloudera Bug: DIR-7655

#### Issues Fixed in Cloudera Director 2.6.0

#### Upgrade from Director 2.4 to 2.5 will fail if a cluster has a heterogeneous instance group

Cloudera Director 2.5 will fail to start after upgrading from 2.4 if a cluster contains a heterogeneous instance group.

Cloudera Bug: DIR-7037

#### Cluster refresh fails on clusters with incompletely allocated instance groups

Users request some number of instances for each instance group. Cloudera Director allows the user to specify a minimum count required for each instance group, which may be less than the requested number of instances. The cluster refresh process fails if an instance group does not contain the requested number of instances.

Cloudera Bug: DIR-7036

## Upgrade from Cloudera Director 2.4 to 2.5 may fail

The database models for clusters with a heterogeneous instance group are not properly updated during upgrade. This will cause Cloudera Director to fail to start.

Workaround: Ensure all instance groups are consistent prior to upgrading to Cloudera Director 2.5. See Ensuring Consistency of Virtual Instance Groups for more information.

#### Cloudera Director Release Notes

#### AWS plugin has broken disk preparation script

Due to a bug in the AWS plugin's disk preparation script, prepare\_unmounted\_volumes, the /data0 directory may be symlinked to the root volume.

Cloudera Bug: DIR-7268

#### Usernames should support user@domain.com format

When "." is used in a username, the Cloudera Director UI fails to create the user. Cloudera Director client does create a user, but the get user and update user commands return 404.

Cloudera Bug: DIR-6896

#### Upgrade from Director 2.4 to 2.5 will fail if a cluster has a heterogeneous instance group

Cloudera Director 2.5 will fail to start after upgrading from 2.4 if a cluster contains a heterogeneous instance group.

Cloudera Bug: DIR-7037

#### Cloudera Director may orphan AWS Spot instances

Cloudera Director tags AWS instances with an instance id. Due to eventual consistency in the AWS API, Cloudera Director may not find the tagged instances during the bootstrap or update process.

Cloudera Bug: DIR-92

#### Issues Fixed in Cloudera Director 2.5.1

#### Custom tag mapping renames user-supplied tag names

The custom tag mapping functionality in the AWS plugin inadvertently renames user-supplied tags as well. For example: if a custom tag mapping is given to rename the "Name" field to "Director\_Name," a user-defined tag of "Name" will also be renamed to "Director Name."

Workaround: Utilize instanceNamePrefixes, which can simulate a custom name, albeit with a UUID at the end of

Cloudera Bug: DIR-6704

#### iptables modules blacklisted during normalization

The iptables.ko and iptables filter.ko modules are blacklisted after instance normalization. This can conflict with applications like Docker, which utilize iptables for their own networking.

Workaround: Delete the /etc/modprobe.d/iptables-blacklist.conf file on each instance using an instance post create script.

Cloudera Bug: DIR-6824

#### Unable to grow cluster when upgrading Cloudera Manager configured with custom repository URLs

If Cloudera Manager in Cloudera Director was upgraded using a non-archive.cloudera.com URL and the cluster is grown, agent installation can fail on the new instances.

Cloudera Bug: DIR-6811

#### Failure of AWS Spot instance allocation may cause bootstrap or update to fail

Cloudera Director deletes Spot instance requests after attempting to allocate Spot instances. A Spot instance request may fail due to AWS API eventual consistency, causing the overall bootstrap or grow process to fail.

Cloudera Bug: DIR-6700

#### Incorrect retrieval of SSH credentials

If the SSH username is overridden in the instance template it can lead to an SSH authentication exception.

Cloudera Bug: DIR-6848

#### The setting preemptiveBasicProxyAuth did not work as expected

The lp.proxy.http.preemptiveBasicProxyAuth setting had no effect before.

Cloudera Bug: DIR-6868

#### Issues Fixed in Cloudera Director 2.5.0

#### AWS IAM permission for RDS required even when RDS not in use

When Cloudera Director validates an environment definition, it performs a call to AWS that requires the rds:DescribeDBSecurityGroups IAM permission. This is true whether or not RDS is to be used for any deployments or clusters in the environment.

Workaround: Include the rds: DescribeDBSecurityGroups permission in the IAM permissions for the user account defined in the environment; if no user is defined, then include the permission in the permission for the IAM role associated with the instance profile of the Director instance.

Cloudera Bug: DIR-2165

# Cloudera Director masks real reason for cluster bootstrap or update failure during host installation

When Cloudera Director tries to add a host to Cloudera Manager, and errors occur that trigger retry, Cloudera Director can produce an exception that includes the following message while retrying:

'JdbcSQLException: Value too long for column "CALL\_STACK'

This is an internal error that masks the root cause, which may be found earlier in the Cloudera Director log, or in the Cloudera Manager log.

Cloudera Bug: DIR-3866

#### Preemptive proxy authentication not working as expected

Preemptive proxy authentication does not work as intended and currently has no effect.

Workaround: Use the proxy without preemptive proxy authentication.

Cloudera Bug: DIR-5354

## Restrictive umask prevents bootstrap

Cloudera Director inappropriately sets the file ownership when creating database scripts for use by Cloudera Manager. When using a more restrictive umask with Cloudera Director, this can prevent deployment bootstrap from succeeding properly.

Workaround: Use the default umask supplied with your filesystem, or use a more permissive umask.

Cloudera Bug: DIR-5394

#### First run fails for cluster with HA enabled for HDFS cloned through Cloudera Director

If you create a non-HA cluster through Cloudera Director with a Cloudera Manager version prior to 5.12, and then enable HA using the Cloudera Manager wizard, Cloudera Director cannot clone the cluster.

Workaround: In order to be able to clone such a cluster, update Cloudera Manager to 5.12 or later, and wait for Cloudera Director to refresh its internal cluster model, before enabling HA through the Cloudera Manager wizard.

#### Presence of external databases prevents deletion of environments

When you delete a database server, we check to see if it is an external db or a registered db. If it is external, we show the delete action: 'Terminate Database Server.' The delete action for an external database should be shown as "Unregister Database Server." Once the external database is unregistered, the environment can be safely deleted.

Cloudera Bug: DIR-5749

#### Refreshing a deployment may overwrite the deployment template

User updates to the deployment template for a deployment may be inadvertently overwritten by refreshing the deployment if they are performed at the same time. This currently only impacts Cloudera Manager credentials.

Workaround: Re-update the Cloudera Manager credentials.

Cloudera Bug: DIR-5851

#### Cloudera Director may fail to repair master roles for certain services when repairing an instance

When repairing an instance with master roles, Cloudera Director may incorrectly attempt to automatically configure those roles instead of running the role migration. This may lead to update failure.

Cloudera Bug: DIR-5862

#### Use numberOfHealthCacheExecutorThreads when provided

Previous versions of Cloudera Director ignored numberOfHealthCacheExecutorThreads when specified in the server configuration file.

Cloudera Bug: DIR-6104

#### Use numberOfCacheExecutorThreads when provided

Previous versions of Cloudera Director ignored numberOfCacheExecutorThreads when specified in the server configuration file.

Cloudera Bug: DIR-6105

#### Terminating cluster creation at the wrong time can leak instances

EC2 instances can potentially leak instances when terminated during deployment or cluster bootstrapping.

Workaround: Delete the leaked instances manually.

Cloudera Bug: DIR-6107

#### Unhealthy host(s) causes 'apply host template' failure when growing the Cluster

When growing an existing cluster, the update operation may fail to add the instances. If the server log shows API call to Cloudera Manager failed. Method=HostTemplatesResource.applyHostTemplate, the user can check the CM API debug logs. One of the reasons for failure could be that the CDH parcel hasn't been activated by the time Cloudera Director attempts to apply the host template. This specific scenario is likely to happen if newly added instances show up as unhealthy in Cloudera Manager, which can cause parcel distribution errors.

Workaround: The best course of action is to try to figure out why the newly-added instance(s) comes up as unhealthy. This can sometimes be fixed by using a different AMI or instance type. If that doesn't work, Cloudera Director's lp.update.sleepTimeForAddInstanceSeconds server property (added in Cloudera Director 2.4.1) can be increased to add additional time for the host to come back as healthy so that the parcel gets distributed and activated before the API call to apply host template.

Cloudera Bug: DIR-6163

#### Shrink operation fails to complete

Host decommissioning can hang in Cloudera Manager, causing a cluster shrink operation to fail to complete successfully.

#### Cluster termination fails during backup of Cloudera Manager configuration files

When a cluster is terminated while Cloudera Director is backing up Cloudera Manager configuration files, it is possible for Cloudera Director to hang attempting to clean up the associated pipelines.

Cloudera Bug: DIR-6221

#### Erroneous error message during cluster creation with Spark 2

When creating a cluster that includes the Spark 2 service with bootstrap-remote, the Cloudera Director client will display the following warning:

```
Found warnings in cluster configuration: Unknown role type:
GATEWAY for service type: SPARK2_ON_YARN in instance group
```

The warning is a false positive, but it does not stop the cluster creation.

Cloudera Bug: DIR-6305

#### Failure to update IP addresses in Cloudera Manager for repaired instances

When repairing instances, Cloudera Director will try to correlate instances known to Cloudera Director with instances known to Cloudera Manager. The correlation is done via the instance's IP address. However if the instance is terminated, the IP address known to Cloudera Director will be a placeholder while Cloudera Manager keeps its original IP address, resulting in failure when attempting to establish the mapping.

Cloudera Bug: DIR-6380

#### Cloudera Director continues trying to update a cluster even if the cluster was terminated in the middle of the update

When updating a cluster, Cloudera Director will first check the cluster status, and compute update steps if it passes the check, and start pipelines to update the cluster with the update steps. However, the check and launching pipelines is not transactional, so if a terminate cluster request is fulfilled in the middle, the update will still kick off the pipeline.

Cloudera Bug: DIR-6391

#### Update fails if 'Redeploy Client Configuration' is checked unnecessarily

Update fails when the Redeploy Client Configuration checkbox on the Modify Cluster page is checked and redeployment of client configurations is not needed.

Workaround: Do not check the Redeploy Client Configuration checkbox if redeployment of the client configuration is not needed.

Cloudera Bug: DIR-6464

#### Cluster bootstrap fails when Spot instance capacity is exceeded

If the number of Spot instances requested exceeds the user's Spot capacity, then the allocation of the Spot instances will fail and cause cluster bootstrap to fail.

Workaround: Ensure your Spot instance limit on your EC2 account is sufficient for the number of instances you request in the specified region.

Cloudera Bug: DIR-6473

#### Cloudera Director may leak instances in AWS

Cloudera Director may retry a failed instance allocation, resulting in two instances tagged with the same ID. Due to the tagging, Cloudera Director may terminate only one of the instances.

Cloudera Bug: DIR-6551

#### Cloudera Director client does not support unicode

HOCON substitution in Cloudera Director configurations is not supported.

#### Cloudera Director Release Notes

Workaround: Write configurations without substitutions.

Cloudera Bug: DIR-5274

#### Block volume limit error reporting

If the EBS volume limit is reached when creating a cluster, the Cloudera Director log might not reflect this root cause, though it might mention creating the cluster failed because it cannot satisfy the minimum threshold limit for specific roles in the cluster.

Cloudera Bug: DIR-5459

#### Issues Fixed in Cloudera Director 2.4.1

#### Errors when using MySQL 5.7 for the Cloudera Director database

The defaults related to TIMESTAMP field handling changed drastically in MySQL 5.7.4 and later, which is documented in SQL Mode Changes in MySQL 5.7 in the MySQL documentation. One of the tables created by Cloudera Director, SERVER\_CONFIGS, conflicts with these new defaults, which were valid in previous versions of MySQL. This is further complicated by the fact that MySQL 5.7.x will allow upgrades from MySQL 5.6 with tables that violate these defaults.

The result is that any modifications attempted on the SERVER CONFIGS table in MySQL 5.7.x will fail. Cloudera Director 2.4 introduced a change to this table, triggering this problem. Additionally, new installs have been observed failing on MySQL 5.7.x due to the SERVER\_CONFIGS table violating the expected defaults.

This issue has been fixed in Cloudera Director 2.4.1 with database changes that:

- Adjust the creation of the SERVER\_CONFIGS table on new installations
- Correct SERVER\_CONFIGS for users upgrading to Cloudera Director 2.4
- Correct SERVER\_CONFIGS for users who have already upgraded to Cloudera Director 2.4

For fresh installations on MySQL 5.7.x, this may affect any version of Cloudera Director starting with version 2.0. For existing installations that are now running on MySQL 5.7.x, this may affect users attempting to upgrade to Cloudera Director 2.4 from Cloudera Director versions 2.0 to 2.3. Running on MySQL 5.5.x or 5.6.x will behave as expected without any database failures.

#### Workarounds:

- Cloudera recommends contacting Cloudera Support in order to fix this issue. However, if that is not an option, the following steps can be used to address the issue.
- · For a fresh install of Cloudera Director, the simplest workaround is to disable strict mode on MySQL. For more information about strict mode and how to disable it, see <u>SQL Server Modes</u> in the MySQL documentation. Using Cloudera Director 2.4.1 will avoid this issue.
- For existing installs, manually modify the MySQL database to avoid this issue:
  - Upgrading from versions lower than 2.0.0: In this case, Cloudera Director will fail when trying to create the SERVER CONFIGS table. In the database housing the Cloudera Director tables, examine the core schema version table and remove the line with the script value V3\_2.0.0\_1\_\_init\_serverconfig.sql.

```
delete from core_schema_version where script = 'V3_2.0.0_1__init_serverconfig.sql';
```

You should see a response like the following:

```
Query OK, 1 row affected (0.02 sec)
```

After this, retry the upgrade using Cloudera Director 2.4.1, or disable strict mode.

Upgrading from versions 2.0.0 to 2.4.0: In this case, Cloudera Director will fail when trying to modify several tables to remove the VERSION column. You must complete the migration manually and fix the TIMESTAMP issue.

```
ALTER TABLE SERVER_CONFIGS MODIFY UPDATED_AT TIMESTAMP NULL, MODIFY CREATED_AT TIMESTAMP
NULL;
ALTER TABLE AUTHORITIES DROP COLUMN VERSION;
ALTER TABLE CLUSTERS DROP COLUMN VERSION;
ALTER TABLE DEPLOYMENTS DROP COLUMN VERSION;
ALTER TABLE ENVIRONMENTS DROP COLUMN VERSION;
ALTER TABLE EXTERNAL_DATABASE_SERVERS DROP COLUMN VERSION;
ALTER TABLE INSTANCE_TEMPLATES DROP COLUMN VERSION;
ALTER TABLE SERVER_CONFIGS DROP COLUMN VERSION;
ALTER TABLE USERS DROP COLUMN VERSION;
UPDATE core_schema_version set success = 1 where script =
'V3_2.4.0_1__remove_versions.sql'
```

One or more of the ALTER TABLE statements may fail with an error that looks like the following:

```
ERROR 1091 (42000): Can't DROP 'VERSION'; check that column/key exists
```

This can be ignored because it was correctly deleted as part of the initial attempt to upgrade to Cloudera Director 2.4.

After this, retry the migration. Cloudera recommends upgrading to Cloudera Director 2.4.1 as soon as possible, although these manual corrections should alleviate the issue.

#### Cloudera Bug: DIR-5921

#### Bootstrap fails because of empty parcel list

Cloudera Director fails in the middle of bootstrap with IllegalArgumentException: Parcel validation failed. This can happen when Cloudera Manager instances take longer than usual to refresh the list of parcels.

#### Cloudera Bug: DIR-6131

# Unhealthy host causes "apply host template" to fail when growing the cluster

When growing an existing cluster the update operation may fail to add the instances. If the server log indicates "API call to Cloudera Manager failed. Method=HostTemplatesResource.applyHostTemplate," the user should enable Cloudera Manager API Debugging and check the server logs in Cloudera Manager to get more information on the failure. See Cloudera Manager API Call Fails in Troubleshooting Cloudera Director for information about checking Cloudera Manager logs.

One of the reasons for failure could be that the CDH parcel wasn't activated by the time Cloudera Director attempted to apply the host template. This specific scenario is likely to happen if newly added instances show up as unhealthy in Cloudera Manager.

Workaround: The best course of action is to try and figure out why the newly added instances comes up as unhealthy. This can sometimes be fixed by using a different AMI or instance type. If that doesn't work, Cloudera Director's lp.update.sleepTimeForAddInstanceSeconds server property can be increased to add additional time for the host to come back as healthy so that parcel gets distributed and activated before the API call to apply host template.

#### Cloudera Bug: None

#### Azure VMs with manually attached Public IPs from different Resource Groups are marked as "not found"

An Azure VM with a manually attached Public IP from a different Resource Group will no longer be marked as "not found" and excluded from the the list of active cluster nodes. As of 2.4.1 the VMs will not report Public IPs from different Resource Groups but they will function as expected otherwise.

Workaround: Create the Public IP for manually attaching to the VM in the same Resource Group as the VM itself.

Cloudera Bug: PARTNER-3927

#### NullPointerException when Cloudera Director retrieves the private FQDN of a VM instance

In some rare cases the OS Profile metadata of an Azure VM can be empty. This can be confirmed by inspecting the VM metadata on Azure Resource Explorer ("osProfile" JSON block will be missing from the VM properties block). The OS Profile contains information such as the VM's private FQDN. An empty OS Profile can be related to Azure VM agents not running correctly on the VM. Cloudera recommends contacting Microsoft Azure support to resolve the issue where OS Profile is empty for an Azure VM. As of Cloudera Director 2.4.1, VM with missing OS Profile will no longer cause NullPointerException.

Cloudera Bug: PARTNER-3992

#### Add D series instances to Azure instance type list

The following instance types are added to to the Azure instance type list:

- Standard D15 v2
- Standard\_D14\_v2
- Standard D13 v2
- Standard\_D12\_v2

Cloudera Bug: PARTNER-3824

#### Expand Error Log for Unsupported Azure VMs

When deploying an unsupported Azure VM type the error message now contains actionable information for how to get and use the latest supported VM types.

Cloudera Bug: PARTNER-3928

#### Shorten Azure VMs Instance ID field in Cloudera Director UI

Azure VMs in Cloudera Director reported their instance IDs as a full Resource ID with Subscription ID and Resource Group name included. As of 2.4.1 the instance ID field is shortened to just the VM name.

Cloudera Bug: PARTNER-3924

#### Use static private IP address assignment option instead of dynamic

To guarantee the private IP address does not change after the VM is deallocated and restarted, the private IP allocation method must be Static. As of 2.4.1 the default private IP address allocation method is changed to Static.

Workaround: Manually change the private IP address assignment option to "Static" for each VM in the cluster via Azure portal.

Cloudera Bug: PARTNER-3914

# Issues Fixed in Cloudera Director 2.4.0

#### Root password for external database server emitted in log

Cloudera Director logs the command line it runs to create new databases for Cloudera Manager and for cluster services. As of version 2.3, the password for the database being created was redacted in these log messages, but the password for the root account of the database server was not. This is fixed in 2.4, and the root password is now also redacted.

Cloudera Bug: DIR-4724

#### Cloudera Director may show the status of a cluster as TERMINATE\_FAILED even when it has successfully terminated

If a cluster is terminated while in the process of bootstrapping, it is possible for the cluster to show TERMINATE\_FAILED even though it has successfully terminated.

#### Cloudera Director does not sync with changes made in Cloudera Manager

Modifying a cluster in Cloudera Manager after it is bootstrapped does not cause the cluster state to be synchronized with Cloudera Director. Services that have been added or removed in Cloudera Manager do not show up in Cloudera Director when growing the cluster. For more information on keeping Cloudera Director and Cloudera Manager in sync, see CDH Cluster Management Tasks.

Cloudera Bug: DIR-1260

#### Old pipeline records not evicted from the Cloudera Director database

Cloudera Director records data about its internal workflow pipelines in its own database. Persisting this information allows Cloudera Director to track pipeline progress across restarts and to resume pipelines that were running or suspended. Pipeline data for old pipelines, such as those that have completed or failed, is automatically evicted from this database. However, under some circumstances, old pipeline data would fail to be evicted, resulting in logged errors. One cause is a Cloudera Director restart, which destroys in-memory pipeline data that was erroneously expected to remain. Cloudera Director 2.4 is more robust and eliminates this cause of pipeline eviction failure.

Workaround: In Cloudera Director 2.3 and below, the inability to evict old pipeline data does not harm Cloudera Director functioning in the short term, but over time the database could grow unacceptably large. Contact Cloudera Support for assistance deleting pipelines that cannot be evicted normally. To prevent build-up of old pipeline data, do not stop Cloudera Director until a round of database eviction is complete.

Cloudera Bug: DIR-5451

#### Delete deployment may orphan underlying clusters

When deleting deployments, it is possible that Cloudera Director deletes a deployment successfully, but leaves the cluster in an undeleted state. Retrying deployment deletion will not help, and the clusters will be orphaned. This is fixed in 2.4 such that a deployment deletion will also check for any orphaned clusters, even if the deployment itself is deleted.

Workaround: In Cloudera Director 2.3 and below, individually delete orphaned clusters if there ID's are known.

Cloudera Bug: DIR-5282

#### Bootstrap fails with non-default password-protected parcel repository

Bootstrap fails when using a password-protected CDH parcel repository with Cloudera Director 2.3 and below. This has been corrected in Cloudera Director 2.4.

Cloudera Bug: DIR-5225

#### Cloudera Director bootstrap hangs if EC2 spot instances terminate immediately after fulfillment

With Cloudera Director 2.3 and below, bootstrap can hang if spot instances terminate immediately after fulfillment, making it necessary to cancel the cluster bootstrap, terminate the cluster, and try again. This has been corrected in Cloudera Director 2.4 such that bootstrap fails immediately.

Cloudera Bug: DIR-5383

#### NullPointerException thrown when creating an invalid environment on Azure

In Cloudera Director 2.3.0 and below, a NullPointerException is thrown when invalid Microsoft Azure environment information (Subscription ID, Tenant ID, Client ID or Client Secret) is used in creating a new Azure Environment. For Cloudera Director 2.4.0 and higher, an error message is shown indicating that invalid Azure environment information was used to create the new Azure environment.

Cloudera Bug: DIR-5187

# Terminated host not properly cleaned up during shrink or repair

When shrinking or repairing an instance that has been terminated outside of Cloudera Director, Cloudera Director may fail to decommission and delete the host from Cloudera Manager.

Cloudera Bug: DIR-5207

#### Terminated EC2 instances report 127.0.0.1 as private IP

AWS instances that were terminated outside of Cloudera Director may have reported an IP address of 127.0.0.1. This has been changed in Cloudera Director 2.4 so that the IP address 192.0.2.1 is reported (an IP address reserved for documentation).

Cloudera Bug: DIR-5386

#### Cloudera Director client infinitely tries to create services if you specify duplicate services

If duplicate services are specified for a cluster (for example, two Hive services or two Impala services), Cloudera Director will infinitely retry to create services during cluster creation.

Cloudera Bug: DIR-4668

Workaround: Cancel the cluster bootstrap, terminate the cluster, and recreate without duplicate services.

#### Cloudera Director may not apply custom configuration to all instances

Cloudera Director requests that Cloudera Manager perform automatic configuration for a cluster prior to applying any custom configurations. Automatic configuration may sometimes create multiple groups of instances within Cloudera Manager for a single corresponding group requested by Cloudera Director. When this occurs, custom configurations for the instances will only be applied to instances in one of the Cloudera Manager groups.

Cloudera Bug: DIR-5030

#### Creation of a cluster where instance groups have no roles is not possible using the web UI

Cloudera Director's web UI does not allow creation of clusters with instance groups that should not have CDH roles deployed on them.

Cloudera Bug: DIR-3991

# Modification of a cluster where instance groups have no roles is not possible using the web UI

Cloudera Director's web UI does not allow modification of clusters with instance groups that should not have CDH roles deployed on them, even if they were created using the API.

Cloudera Bug: DIR-3955

#### Cluster launch fails using the development version of Cloudera Manager 5.10 and CDH 5.10 with Kudu

Cloudera Director 2.3 does not support deployment and management of Kudu.

Cloudera Bug: DIR-4854

If a cluster is terminated while it is bootstrapping, the cluster must be terminated again to complete the termination

Terminating a cluster that is bootstrapping stops ongoing processes but keeps the cluster in the bootstrapping phase.

Cloudera Bug: None

## Issues Fixed in Cloudera Director 2.3.0

#### Deployment bootstrap process may fail to complete

The process of bootstrapping a deployment can hang indefinitely waiting for Cloudera Manager to start, even after Cloudera Manager is up and reachable.

#### Cloudera Director does not install the JDBC driver for an existing MySQL database

Cloudera Director automatically installs JDBC drivers on an instance for Cloudera Manager and the CDH clusters it provisions. However, when you use an existing MySQL database with Cloudera Manager, Cloudera Director does not install the JDBC driver, which can result in database connection failures.

Cloudera Bug: DIR-3867

#### External databases are not configured for Hue and Oozie

External databases are not configured for Hue and Oozie in clusters created through the Cloudera Director web UI.

Cloudera Bug: DIR-3984

#### Normalization process does not set swappiness correctly on RHEL 7.2

On CentOS/RHEL 7 operating systems, the tuned service overwrites the swappiness settings that Cloudera Director configures on instances.

Cloudera Bug: DIR-3993

#### Stale service configs

Cloudera Director sometimes fails to detect stale services properly when restarting a cluster.

Cloudera Bug: DIR-4417

#### The nscd tool is installed but not enabled during normalization

nscd, a tool which caches common name service requests, is installed on Cloudera Director-managed instances, but is not enabled on CentOS and RHEL. This can reduce the performance of the bootstrapping process.

Cloudera Bug: DIR-4627

## Cluster update or termination during instance metadata refresh fails to complete

If a deployment or cluster is terminated or updated at the same time that a refresh of instance metadata is running, on rare occasions the refresh will prevent the terminate or update operation from completing properly.

Cloudera Bug: DIR-5145

#### Director detects SRIOV incorrectly

For AWS instances, Cloudera Director will always report Enhanced Networking (SR-IOV) as false (for example on the instance properties page), even when it's enabled. This is fixed in Cloudera Director 2.3 and requires IAM permissions for the EC2 method DescribeInstanceAttribute.

Cloudera Bug: DIR-4997

#### After Cloudera Manager bootstrap failure, termination leads to renewed bootstrap attempt

In Cloudera Director 2.2, if you attempt to terminate a cluster or deployment in the BOOTSTRAP FAILED stage, it may go back into the BOOTSTRAPPING stage and return the following exception message:

java.util.concurrent.TimeoutException: Pipeline did not complete in 10 SECONDS.Inthissituation, terminating the deployment or cluster a second time should terminate the cluster or deployment as expected. This can also happen in Cloudera Director 2.1, but the exception message will be the following more generic message: 500 internal server error.

Cloudera Bug: DIR-4263

# Warning when adding Hue Load Balancer role

When you bootstrap or validate a cluster that has the HUE\_LOAD\_BALANCER role, Cloudera Director generates an unknown role type warning for the role.

#### Bootstrap failure with Kafka and Sentry on Cloudera Manager 5.9

Cluster bootstrap fails when using Cloudera Manager 5.9 with both Kafka 2.0 and Sentry.

If Kafka and Sentry are required on the same cluster, use one of the following combinations:

- Kafka 2.1 with Cloudera Manager 5.9 or 5.10
- Kafka 2.0 with Cloudera Manager 5.8 or lower

Cloudera Bug: DIR-4634

#### Lack of support for newer AWS regions

When selecting certain AWS regions, such as ap-northeast-2, an error message can appear stating Unable to find the region ap-northeast-2. In this case, manually set the KMS region endpoint (under Advanced Options) to the KMS region endpoint specified in the <u>AWS Regions and Endpoints</u> in the AWS documentation.

Cloudera Bug: DIR-4978

#### Cloudera Manager repository URL validation failure

The validation of the Cloudera Manager repository can fail during the bootstrap process if the URL uses a host like localhost, a single-word hostname, or one with an internal or non-standard domain name. Use an IP address for the host, or use a hostname with a common domain like . com.

Cloudera Bug: DIR-4962

#### Cloudera Director configures Hue to use SQLite

CDH 5.8 and higher installs Postgres drivers along with Hue. When configuring a cluster to use Cloudera Manager's embedded Postgres database, Director will configure Hue to use its own embedded SQLite database rather than Cloudera Manager's embedded Postgres database.

Cloudera Bug: DIR-4952

#### MySQL database creation fails with insufficiently strong password

When using MySQL 5.7 as an external database server for a Cloudera Director deployment or cluster, database creation may fail with an error: "Your password does not satisfy the current policy requirements." This is due to Cloudera Director generating random UUIDs for passwords, which do not satisfy the MEDIUM level of password validation in MySQL 5.7. Disable password validation in MySQL, or adjust the validation level to LOW.

Cloudera Bug: DIR-4936

# RDS instance creation fails with password length violation

AWS RDS requires a master user password of at least eight characters. If a password is supplied that is too short, Cloudera Director fails to validate it, leading to a failure from RDS. Ensure that the master user password is at least eight characters long.

Cloudera Bug: DIR-4916

#### Cloudera Manager server logs in Diagnostic data may be empty

Cloudera Director automatically attempts to collect diagnostic data after cluster bootstrap failure. If cluster bootstrap failed before or just after the cluster is created in Cloudera Manager, then the scm-server-logs inside the diagnostic data may be empty. In this case, trigger diagnostic data collection on the deployment.

Cloudera Bug: DIR-4877

#### High Azure Standard Storage Disk Usage

Azure Standard Disks are billed for used space + transactions (see Azure Storage Standard Disk Pricing). In Cloudera Director 2.2, Standard Storage Virtual Hard Disks (VHDs) are mounted without the "discard" option. As a result, if a file is deleted on the VHD it does not release this space back to Azure Standard Storage and it will continue to be billed as used space. Note: this issue does not cause disk space leakage; space occupied by deleted files can still be used by new files.

To address this problem, edit the prepare\_unmounted\_volumes file to add the discard mount option. prepare\_unmounted\_volumes is located at

/var/lib/cloudera-director-plugins/azure-provider-1.1.0/etc/.

#### Change line 78 from:

```
echo "UUID=${blockid} $mount $FS defaults, noatime 0 0" >> /etc/fstab
```

to

```
echo "UUID=${blockid} $mount $FS defaults, noatime, discard 0 0" >> /etc/fstab
```

Restart the Cloudera Director server service after making this change.

Cloudera Bug: DIR-4719

#### Java Clients return null for a 404 ("Not Found") response

The Java client currently can return null values for both 204 and 404 response codes from the collectDiagnosticData service endpoint. Therefore, it is difficult to tell if a collection call fails because a deployment or cluster is missing. In this case, poll for the status for a finite amount of time. If the poll times out, consider the collection attempt failed.

Cloudera Bug: DIR-4628

#### Incorrect choice of response code for cluster update failure

An API request to update a cluster fails if the cluster is in transition, for example, if it is already being updated. The response code for the failure, however, is 204, which indicates success.

Cloudera Bug: DIR-4496

#### Environments may not be able to be deleted temporarily

Even when an environment is empty, that is, all of its deployments and external databases have been deleted, it can take five to ten minutes before it is possible to delete the environment. This is due to remaining data structures that have not yet been automatically cleaned up.

Cloudera Bug: DIR-4438

# SELinux remains enabled on instances allocated by Director

Depending on the operating system, Cloudera Director may misread the state of SELinux on instances it allocates and determine that it is disabled, when it is actually still enabled. This can lead to errors running Cloudera Manager or cluster services.

Cloudera Bug: DIR-4425

#### Security group validation should be configurable

This change provides a new capability for end users to enforce network requirements. It allows users to define the network rules configuration and validates AWS security groups against the pre-defined rules. When writing rules, users can not only define allowed networking traffic, but also deny traffic against specific ports from a list of IP ranges.

Cloudera Bug: DIR-4339

# Time daemons do not run properly on RHEL and CentOS 7.x instances

The choice of standard time daemon for RHEL and CentOS 7.x releases has changed from ntpd to chronyd. However, Cloudera Director does not perform the correct commands when normalizing instances to properly set up chronyd. Instances may end up with ntpd running, or no time daemon running at all. To avoid this, rely on ntpd for time

#### Cloudera Director Release Notes

synchronization, and use an instance bootstrap script to disable chronyd and enable ntpd. For more information, see Configuring NTP Using NTPD in the Red Hat Linux 7 System Administrator's Guide.

Cloudera Bug: DIR-3994

#### Issues Fixed in Cloudera Director 2.2.0

#### Storage Encryption for AWS RDS Instances

Before Cloudera Director 2.2, storage encryption for AWS RDS instances was not supported, despite the presence of a KMS key ID field in the web UI form for describing RDS instances. The web UI field was ignored. In Cloudera Director 2.2, storage encryption is supported, using the default key ID associated with RDS for the AWS account. Use of a non-default KMS key is not supported, and the KMS key ID field has been removed from the web UI. See Defining External Database Servers for information on enabling storage encryption for a new RDS instance.

Cloudera Bug: DIR-1407

#### Cannot update environment credentials of environments deployed on Microsoft Azure

With Cloudera Director on Microsoft Azure, the Update Environment Credentials web UI displays only some properties, and does not display all the properties required for the update.

Cloudera Bug: DIR-4072

#### Azure operation timeout

Some Azure operations, such as VM creation and deletion, can take longer to complete than the default timeout value of 20 minutes. When this occurs, the Cloudera Director Azure plugin will timeout the Azure operation, resulting in a failure to complete the operation. Adjusting the Cloudera Director server timeout does not help.

Wait until Azure operation time drops back to normal range (less than 20 minutes).

Affected Versions: Cloudera Director 2.1.0, 2.1.1. Beginning in Cloudera Director 2.2.0, the user can change the timeout value for Azure if the default value of 20 minutes is not long enough.

Cloudera Bug: PARTNER-2860

#### Deployment fails on Azure due to incompatible instance type existing in an Availability Set

VM creation fails if the VM of one series (for example, DS13) is deployed into an Azure Availability Set that already contains one or more VMs from a different series (for example, DS13\_V2). This is an Azure platform restriction.

Affected Versions: Cloudera Director 2.1.0, 2.1.1. Beginning in Cloudera Director 2.2.0, an error is reported when an instance template is created that will cause a VM to be deployed into an incompatible Availability Set.

Cloudera Bug: PARTNER-2941

#### Add check to make sure resources are in the same region

VM creation fails when using resources from one region (for example, a VNET in EastUS) to deploy a VM in another region (for example, WestUS). This is an invalid configuration yet it may not be obvious when configuring an instance template.

Affected Versions: Cloudera Director 2.1.0, 2.1.1. Beginning in Cloudera Director 2.2.0, an error will be shown if the user tries to configure an instance template with resources from a different region than what is defined at the environment level.

Cloudera Bug: PARTNER-2952

## Some valid host FQDN suffixes are not allowed in the Azure instance template

The regex check for the host FQDN suffix (DNS domain on the private cluster network) does not allow valid host FQDN with fewer than three characters. For example, company.us is not allowed.

Affected Versions: Cloudera Director 2.1.0, 2.1.1. Beginning in Cloudera Director 2.2.0, the check for host FQDN has been relaxed to allow names like company.us or company.1.us.

Cloudera Bug: PARTNER-3106

# Merge user-provided image configuration files with internal ones

Updating a Cloudera Director Azure plugin configuration file (images.conf) requires replacing the entire configuration file, even if only part of the configuration file needs to be updated.

Affected Versions: Cloudera Director 2.1.0, 2.1.1. Beginning in Cloudera Director 2.2.0, the user can provide partial Azure plugin configuration files containing only the portions to be updated.

Cloudera Bug: PARTNER-2567

#### Issues Fixed in Cloudera Director 2.1.1

#### Cloudera Director cannot connect to restarted VMs on Azure

Restarted VMs on Microsoft Azure are sometimes assigned a new IP address. This causes the cached IP address in Cloudera Director to become stale, so that Cloudera Director is unable to connect to the VMs.

Affected Version: Cloudera Director 2.1.0.

Cloudera Bug: PARTNER-2607

#### Public IP attached to a VM on Azure is deleted when the VM is deleted

Any public IP attached to a VM is deleted when the VM is deleted, even if that public IP was not created by the plugin.

Affected Version: Cloudera Director 2.1.0.

Cloudera Bug: PARTNER-2617

#### Cloudera Director web UI handles errors incorrectly with failed instance template validation on Azure

When the Microsoft Azure subscription permissions are not properly set up, an unexpected error can occur, causing instance template validation to exit. This error is not properly displayed in the Cloudera Director web UI.

Affected Version: Cloudera Director 2.1.0.

Cloudera Bug: PARTNER-2805

#### Resource name cannot contain special characters

A deployment may fail if the compute resource group used for Azure deployment contains special characters such as an underscore ( ). Resource group names are sometimes used in the construction of resource names, causing deployments to fail if the resource group names contain special characters, because the naming restrictions are different for resource group names and resource names.

Affected Version: Cloudera Director 2.1.0.

Cloudera Bug: PARTNER-2848

# Bootstrapping of clusters may fail if configured to not associate public IP addresses with EC2 instances

When using AWS, if the user deselects the Associate public IP addresses checkbox, instructing Cloudera Director to not assign public IP addresses to the EC2 instances it creates, Cloudera Director incorrectly interprets the missing public IP address of each instance as localhost (the Cloudera Director instance itself). Under certain conditions, this can lead to a variety of errors, including bootstrap failures and corruption of the Cloudera Director instance.

Affected Version: Cloudera Director 2.1.0.

Cloudera Bug: DIR-3713

#### Cloudera Director Release Notes

#### Database server password fails if it contains special characters

Cloudera Director server does not handle special characters properly in database server admin/root passwords.

Cloudera Bug: DIR-3622

#### Update Cloudera Manager Credentials fails in certain scenarios

Cloudera Director erroneously rejects the credentials update as an unsupported modification if sensitive fields are configured on the deployment. The sensitive fields include license, billingId, and krbAdminPassword.

Cloudera Bug: DIR-3879

#### Cloudera Director server fails to start after upgrade under some circumstances

During an upgrade, Cloudera Director expects the Cloudera Manager instances it has deployed to match the instance template that was used while bootstrapping those instances. If the instance was modified out of band of Cloudera Director, then the server fails to start. An example of a mismatch is if the instance type of the Cloudera Manager instance was modified from within the cloud provider console.

Cloudera Bug: DIR-3956

#### Cluster bootstrap fails with high task parallelism

For high values of lp.bootstrap.parallelBatchSize, Cloudera Director fails to bootstrap clusters and throws an exception indicating that it failed to write intermediate state to the database. The default value of lp.bootstrap.parallelBatchSize is 20. lp.bootstrap.parallelBatchSize controls how many operations Cloudera Director should do in parallel while configuring a cluster.

Cloudera Bug: DIR-3771

# Modifying a cluster can leave some roles marked as stale in Cloudera Manager

When growing or shrinking a cluster, you are presented with the option of restarting the cluster. The restart operation should only restart roles that are marked stale by Cloudera Manager, that is, only roles that need to be restarted. This optimization serves to minimize cluster downtime. However, with Cloudera Director 2.1.x, some stale roles might not be restarted, even though the **Restart Cluster** option is selected.

Cloudera Bug: DIR-3466

# Default memory autoconfiguration for monitoring services may be suboptimal

Depending on the size of your cluster and your instance types, you may need to manually increase the memory limits for the Host Monitor and Service Monitor. Cloudera Manager displays a configuration validation warning or error if the memory limits are insufficient.

Cloudera Bug: DIR-2205

# Issues Fixed in Cloudera Director 2.1.0

# Validation error after initial setup with high availability

When you set up HDFS high availability using Cloudera Director, the secondary NameNode is not configured, because it is not required for high availability. Because of a Cloudera Manager bug, the absence of a secondary NameNode causes an erroneous validation error to appear in Cloudera Manager in HDFS > Configuration > HDFS Checkpoint Directories.

Cloudera Bug: DIR-1893

# Repository or parcel URLs with internal domain names fail validation

Repository or parcel URLs fail validation in Cloudera Director when they are specified with internal domain names.

Cloudera Bug: DIR-2794

# Database-related error when running Cloudera Director CLI after upgrade

When run after upgrade, the Cloudera Director CLI performs steps to upgrade its local database from the previous version. It can report an error:

Referential integrity management for DEFAULT not implemented.

Cloudera Bug: DIR-3587

# Cloudera Director Does Not Recognize Cloudera Manager Password Changes

Cloudera Director does not recognize changes in the admin password in Cloudera Manager unless the username associated with the new password is also changed.

Cloudera Bug: DIR-2868

#### Incorrect yum repo definitions for Google Compute Engine RHEL images

The default RHEL 6 image defined in director-google-plugin version 1.0.1 and lower has an incorrect yum repo definition. This causes yum commands to fail after yum caches are cleared. See the Google Compute Engine issue tracker for issue details.

Cloudera Bug: DIR-2669

# Long version string required for Kafka

Kafka requires a nonintuitive version string to be specified in the configuration file or web UI.

Cloudera Bug: DIR-2298

#### Issues Fixed in Cloudera Director 2.0.0

#### Cloning and growing a Kerberos-enabled cluster fails

Cloning of a cluster that uses Kerberos authentication fails, whether it is cloned manually or by using the kerberize-cluster.py script. Growing a cluster that uses Kerberos authentication fails.

Cloudera Bug: DIR-1614

#### Kafka with Cloudera Manager 5.4 and lower causes failure

Kafka installed with Cloudera Manager 5.4 and lower causes the Cloudera Manager installation wizard, and therefore the bootstrap process, to fail, unless you override the configuration setting broker\_max\_heap\_size.

Cloudera Bug: DIR-2240

#### Cloudera Director does not set up external databases for Oozie and Hue

Cloudera Director cannot set up external databases for Oozie and Hue.

Cloudera Bug: DIR-996

# Issues Fixed in Cloudera Director 1.5.2

#### Apache Commons Collections deserialization vulnerability

Cloudera has learned of a potential security vulnerability in a third-party library called the Apache Commons Collections. This library is used in products distributed and supported by Cloudera ("Cloudera Products"), including Cloudera Director. At this time, no specific attack vector for this vulnerability has been identified as present in Cloudera Products.

The Apache Commons Collections potential security vulnerability is titled "Arbitrary remote code execution with InvokerTransformer" and is tracked by COLLECTIONS-580. MITRE has not issued a CVE, but related CVE-2015-4852 has been filed for the vulnerability. CERT has issued Vulnerability Note #576313 for this issue.

#### Cloudera Director Release Notes

Releases affected: Cloudera Director 1.5.1 and lower, CDH 5.5.0, CDH 5.4.8 and lower, Cloudera Manager 5.5.0, Cloudera Manager 5.4.8 and lower, Cloudera Navigator 2.4.0, and Cloudera Navigator 2.3.8 and lower

Users affected: All

Severity (Low/Medium/High): High

Impact: This potential vulnerability may enable an attacker to run arbitrary code from a remote machine without requiring authentication.

Immediate action required: Upgrade to Cloudera Director 1.5.2, Cloudera Manager 5.5.1, and CDH 5.5.1.

Serialization for complex nested types in Python API client

Serialization for complex nested types has been fixed in the Python API client.

#### Issues Fixed in Cloudera Director 1.5.1

#### Support for configuration keys containing special characters

Configuration file parsing has been updated to correctly support quoted configuration keys containing special characters such as colons and periods. This enables the usage of special characters in service and role type configurations, and in instance tag keys.

#### Issues Fixed in Cloudera Director 1.5.0

# Growing clusters may fail when using a repository URL that only specifies major and minor versions

When using a Cloudera Manager package repository or CDH/parcel repository URL that only specifies the major or minor versions, Cloudera Director may incorrectly use the latest available version when trying to grow a cluster.

For Cloudera Manager: https://archive.cloudera.com/cm5/redhat/6/x86\_64/cm/5.3.3/

For CDH: https://archive.cloudera.com/cdh5/parcels/5.3.3/

Cloudera Bug: DIR-1482

# Flume does not start automatically after first run

Although you can deploy Flume through Cloudera Director, you must start it manually using Cloudera Manager after Cloudera Director bootstraps the cluster.

Cloudera Bug: DIR-779

# Impala daemons attempt to connect over IPv6

Impala daemons attempt to connect over IPv6.

Cloudera Bug: DIR-939

DNS queries occasionally time out with AWS VPN

DNS queries occasionally time out with AWS VPN.

Cloudera Bug: DIR-972

#### Issues Fixed in Cloudera Director 1.1.3

# Ensure accurate time on startup

Instance normalization has been improved to ensure that time is synchronized by Network Time Protocol (NTP) before bootstrapping, which improves cluster reliability and consistency.

Cloudera Bug: DIR-1424

#### Speed up ephemeral drive preparation

Instance drive preparation during the bootstrapping process was slow, especially for instances with many large ephemeral drives. Time required for this process has been reduced.

Cloudera Bug: DIR-1265

#### Fix typographical error in the virtualization mappings. properties file

The d2 instance type d2.4xlarge was incorrectly entered into Cloudera Director as d3.4xlarge in virtualizationmappings.properties. This has been corrected.

Cloudera Bug: DIR-1326

# Avoid upgrading preinstalled Cloudera Manager packages

Cloudera Director no longer upgrades preinstalled Cloudera Manager packages.

Cloudera Bug: DIR-1370

#### Issues Fixed in Cloudera Director 1.1.2

# Parcel validation fails when using HTTP proxy

Parcel validation now works when configuring an HTTP proxy for Cloudera Director server, allowing correctly configured parcel repository URLs to be used as expected.

Cloudera Bug: DIR-1251

# Unable to grow a cluster after upgrading Cloudera Director 1.0 to 1.1.0 or 1.1.1

Cloudera Director now sets up parcel repository URLs correctly when a cluster is modified.

Cloudera Bug: DIR-1247

# Add support for d2 and c4 AWS instance types

Cloudera Director now includes support for new AWS instance types d2 and c4. Cloudera Director can be configured to use additional instance types at any point as they become available in AWS.

Cloudera Bug: DIR-1070

#### Issues Fixed in Cloudera Director 1.1.1

# Service-level custom configurations are ignored

Restored the ability to have service-level custom configurations. Due to internal refactoring changes, it was no longer possible to override service-level configs.

Cloudera Bug: DIR-1198

# The property customBannerText is ignored and not handled as a deprecated property

Restored the customBannerText configuration file property, which was removed during the internal refactoring work.

Cloudera Bug: DIR-1199

# Fixed progress bar issues when a job fails

The web UI showed a progress bar even when a job had failed.

Cloudera Bug: DIR-1073

# Updated IAM Help text on Add Environment page

The help text on the Add Environment page for Role-based keys should refer to AWS Identity and Access Management (IAM), not to AMI.

# Cloudera Director Release Notes

Cloudera Bug: DIR-1122

Add eu-central-1 to the region dropdown

The eu-central-1 region has been added to the region dropdown on the Add Environment page.

Cloudera Bug: DIR-1146

Gateway roles should assign YARN, HDFS, and Spark gateway roles

All available gateway roles, including YARN, HDFS, and Spark, should be deployed by default on the instance.

Cloudera Bug: DIR-1114

Spark on YARN should be shown on the Modify Cluster page

Spark on YARN did not appear in the list of services on the Modify Cluster page.

Cloudera Bug: DIR-1115

# Requirements and Supported Versions

The following sections describe the requirements and supported operating systems, databases, and browsers for Cloudera Director.

# **Cloud Providers**

Cloudera Director has native support for Amazon Web Services (AWS), Google Cloud Platform, and Microsoft Azure.

Each Cloudera Director release embeds the current plug-in for supported cloud providers, but a newer plug-in may have been posted on the Cloudera GitHub site subsequent to the Cloudera Director release. To check for the latest version, click the appropriate link:

- AWS cloud provider plug-in
- Google Cloud Platform cloud provider plug-in
- Microsoft Azure cloud provider plug-in

# Cloudera Director Service Provider Interface (SPI)

The Cloudera Director SPI defines an open source Java interface that plug-ins implement to add support for additional cloud providers to Cloudera Director. For more information, see the README.md file in the SPI Cloudera Director GitHub repository.

# **Supported Software and Distributions**

The table below lists software requirements, recommendations, and supported versions for resources used with Cloudera Director.

	Cloudera Director	Cloudera Manager and CDH
Operating Systems (64-bit only)	RHEL and CentOS 6.5, 6.7, 6.8, 7.1, 7.2, and 7.3  Ubuntu 14.04	For AWS and Google Cloud Platform: RHEL and CentOS 6.5, 6.7, 6.8, 7.1, 7.2, and 7.3  Spot instances: AWS supports Spot instances only on Centos operating systems, not on RHEL.  For Microsoft Azure: RHEL and CentOS 6.7, 6.8, and 7.2
		RHEL 7.2 is supported only for Cloudera Manager and CDH 5.7 and higher. RHEL 7.3 (on AWS) is supported only for Cloudera Manager and CDH 5.10 and higher.
		To use Amazon EC2 D2 instances, you must run a minimum version of RHEL 6.7 or CentOS 6.7. Earlier versions of RHEL and CentOS do not support these instance types.
Oracle Java SE Development Kit (JDK)	Oracle JDK version 7 or 8	Oracle JDK version 7 or 8

	Cloudera Director	Cloudera Manager and CDH
	For download and installation information, see <u>Java SE Downloads</u> .	
Default Database	Embedded H2 database (not recommended for production use)	Embedded PostgreSQL Database (not recommended for production use)
Supported Databases	MySQL 5.5, 5.6, 5.7	MySQL 5.5, 5.6, 5.7
	MariaDB 5.5	MariaDB 5.5
		PostgreSQL 8.1, 8.3, 8.4, 9.1, 9.2, 9.3, 9.4, 9.5

Note: In production environments, you should use an external MySQL or MariaDB database for Cloudera Director. For information on using an external MySQL database in place of the H2 embedded database, see Using MySQL for Cloudera Director Server on page 115. For information on using an external MariaDB database in place of the H2 embedded database, see Using MariaDB for Cloudera <u>Director Server</u>. By default, Cloudera Director stores its environment and cluster data in the embedded H2 database located at /var/lib/cloudera-director-server/state.h2.db. Back up this file to avoid losing the data. Cloudera strongly recommends using MySQL or MariaDB for production deployments of Cloudera Director, instead of H2. Use of the H2 database in production environments can result in excessive space consumption for database files and slow database access. Unlike managed MySQL and MariaDB databases, H2 files are not backed up regularly, which puts your production deployment of Director at risk of data loss.

Note: The versions of PostgreSQL listed above are supported with Cloudera Manager and CDH 5.11. Setting up PostgreSQL via Amazon RDS for Cloudera Manager and CDH is not supported. For a table of PostgreSQL versions supported with earlier versions of Cloudera Manager and CDH, see the PostgreSQL section of <u>CDH and Cloudera Manager Supported Databases</u> in the Cloudera Enterprise release notes. For information on setting up external database servers and on creating databases on existing database servers, see Using an External Database for Cloudera Manager and CDH on page

Note: To run Kafka and Sentry on the same cluster, you must use Kafka 2.1 with Cloudera Manager and CDH 5.9 or 5.10.

**Note:** For the latest information on operating system versions supported on Microsoft Azure, refer to the Cloudera Reference Architecture for Microsoft Azure Deployments.

# Resource Requirements

The table below lists requirements for resources used with Cloudera Director.

	Cloudera Director	Cloudera Manager and CDH
СРИ	2	4
RAM	3.75 GB	64 GB
Disk	8 GB	500 GB

	Cloudera Director	Cloudera Manager and CDH
Recommended AWS instance	c3.large or c4.large	Cloudera Manager: m4.xlarge or m4.4xlarge
Recommended Google Cloud Platform instance	n1-standard-2	n1-highmem-4 or n1-highmem-8
Recommended Microsoft Azure instance	Standard_D3 or larger	The following Azure instance types are supported:  Standard_D12_v2 Standard_D13_v2 Standard_D14_v2 Standard_D15_v2 Standard_DS12_v2 Standard_DS13_v2 Standard_DS13_v2 Standard_DS14_v2 Standard_DS14 Standard_DS14 Standard_DS15_v2 Standard_DS15_v2 Standard_GS5

Note: For the latest information on instance types supported on Microsoft Azure, refer to the Cloudera Reference Architecture for Microsoft Azure Deployments.

Note: The recommended instance for Cloudera Manager depends on the workload. Some instance types may not be available in every region. Cloudera Director does not dynamically validate instance type by region. Contact your Cloudera account representative for more information.

# Supported Cloudera Manager and CDH Versions

Cloudera Director 2.6 can install any version of Cloudera Manager 5 with any CDH 5 parcels. Use of CDH packages is not supported.

If you are using Cloudera Director 2.6 to deploy Cloudera Manager and CDH, the latest released version of Cloudera Manager 5.13 and CDH 5.13 is installed by default. To use any other version of Cloudera Manager or CDH, follow the instructions for installing non-default versions of Cloudera Manager and CDH in the Getting Started section for your cloud provider:

- For AWS, see <u>Deploying Cloudera Manager and CDH on AWS</u> on page 57.
- For Google Cloud Platform, see <u>Deploying Cloudera Manager and CDH on Google Compute Engine</u> on page 71.
- For Microsoft Azure, see <u>Deploying Cloudera Manager and CDH on Microsoft Azure</u>.

# **Networking and Security Requirements**

Cloudera Director recommends the following inbound ports to be open:

- TCP ports 22: These ports allow SSH to Cloudera Director instance.
- All traffic across all ports within the security group: This rule allows connectivity with all the components within the Hadoop cluster. This rule avoids numerous individual ports to be opened in the security group.

# Requirements and Supported Versions

Туре	Protocol	Port Range	Source
SSH (22)	TCP (6)	22	0.0.0.0/0
ALL Traffic	ALL	ALL	security_group_id
			See note paragraph below.

Note: In AWS, the All traffic rule above requires the security group ID. If you create a security group from scratch, create the security group with the SSH rule and then go back and edit the security group to allow all traffic within the security group.

To connect to the AWS network, Cloudera recommends that you open only these ports and set up a SOCKS proxy. Unless your network has direct connection to AWS, you must set this up to access the Cloudera Director instance. This is done in a later step.

In a restricted network environment, you may want to enable minimal network traffic between instances and keep open ports to a minimum rather than enabling all network traffic between cluster instances. For information about minimal port requirements, see Ports Used by Cloudera Director.

# Supported Browsers

Cloudera Director supports the following browsers:

- Mozilla Firefox 11 and higher
- Google Chrome
- Internet Explorer 9 and higher
- Safari 5 and higher

# Getting Started with Cloudera Director

This section explains how to get Cloudera Director up and running on Amazon Web Services (AWS), Google Cloud Platform, and Microsoft Azure.

# Getting Started on Amazon Web Services (AWS)

To use Cloudera Director on AWS, you create an environment in Amazon Virtual Private Cloud (Amazon VPC), start an instance in AWS to run Cloudera Director, and create a secure connection. This section describes the steps for each of these tasks.

#### Important:

Cloudera Director supports Spot instances. Spot instances are virtual machines that have a lower cost but are subject to reclamation at any time by AWS. Because of the possibility of interruption, Cloudera recommends that you use Spot instances only for worker roles in a cluster, not for master or gateway roles. AWS only supports Spot instances on CentOS, not on RHEL.

For more information about using Spot instances with Cloudera Director, see Using Spot Instances.

# Setting up the AWS Environment

You must set up a VPC and create an SSH key pair in the AWS environment before deploying Cloudera Director.

#### Setting Up a VPC

Cloudera Director requires an Amazon Virtual Private Cloud (Amazon VPC) to implement its virtual environment. The Amazon VPC must be set up for forward and reverse hostname resolution.

Perform the following steps:

- 1. Log in to the AWS Management Console and make sure you are in the desired region. The current region is displayed in the upper-right corner of the AWS Management Console. Click the region name to change your region.
- 2. In the AWS Management Console, select VPC in the Networking section.
- 3. Click Start VPC Wizard. (Click VPC Dashboard in the left side pane if the Start VPC Wizard button is not displayed.)
- 4. Select the desired VPC configuration. For the easiest way to get started, select VPC with a Single Public Subnet. Make sure that **DNS Hostnames** is set to **Yes** in the **Edit DNS Hostnames** dialog.
- **5.** Complete the VPC wizard, and then click **Create VPC**.

#### Configuring your Security Group

Cloudera Director requires the following inbound ports to be open:

#### Table 1: Ports

Туре	Protocol	Port Range	Source
ALL Traffic	ALL	ALL	security_group_id
SSH (22)	TCP (6)	22	<your address="" ip=""></your>

Note: By default, Cloudera Director requires unrestricted outbound connectivity. You can configure Cloudera Director to use proxy servers or a local mirror of all the relevant repositories if required.

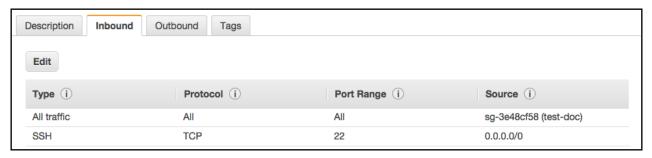

#### Creating a New Security Group

The simplest way to set up the required network connectivity for Cloudera Director is to create a security group for your VPC and allow traffic between members of this security group as described below. With this approach, you do not have to specify each part that is required by Cloudera Manager.

- 1. In the left pane, click Security Groups.
- 2. Click Create Security Group.
- 3. Enter a name and description. Make sure to select the VPC you created from the VPC list box.
- 4. Click Yes, Create.

Select the newly created security group and add inbound rules as detailed in the Ports table.

The configured security group should look similar to the following, but with your own values in the Source column.

For more information about security groups in AWS, see Security Groups for Your VPC. If your organization's network policies are more restrictive, and you need to specify each port required by Cloudera Manager, see Ports Used by Cloudera Manager and Cloudera Navigator in the Cloudera Manager documentation for details.

#### Creating an SSH Key Pair

To interact with the cluster launcher and other instances, you must create an SSH key pair or use an existing EC2 key pair. For information on importing an existing key pair, see Amazon EC2 Key Pairs in the AWS documentation. If you do not have a key pair, follow these steps:

- 1. Select EC2 in Compute section of the AWS console.
- 2. In the Network & Security section of the left pane, click Key Pairs.
- 3. Click Create Key Pair. In the Create Key Pair dialog box, enter a name for the key pair and click Create.
- 4. Note the key pair name. Move the automatically downloaded private key file (with the . pem extension) to a secure location and note the location. For Mac OS X, the key pair file is initially stored in the **Downloads** folder.
  - On Mac OS X, a secure location for storing the private key file is the hidden ~/ .ssh folder.
  - Enter the following command in a terminal window to move the key pair file from the Downloads folder to the SSH folder:

```
$ mv name_of_key_pair.pem ~/.ssh
```

You are now ready to launch an EC2 instance.

# Launching an EC2 Instance for Cloudera Director

On AWS, Cloudera Director requires a dedicated Amazon EC2 instance. The simplest approach is to create this instance in the same VPC and subnet where you want Cloudera Director to create new instances for Cloudera Manager and your CDH clusters.

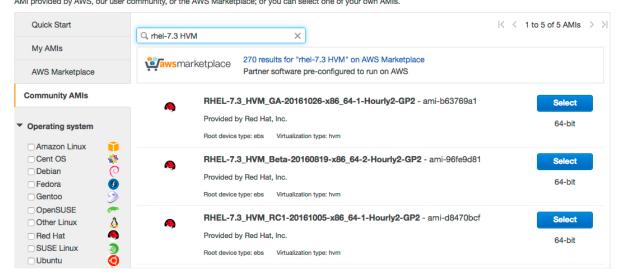

Note: Alternatively, you can install Cloudera Director in a different region, on a different cloud provider, or a different network environment. For information on these more complex setups, see Running Cloudera Director and Cloudera Manager in Different Regions or Clouds on page 112.

To create the instance, follow these steps:

- 1. In the AWS Management Console, select EC2 from the Services navigation list box in the desired region.
- 2. Click the Launch Instance button in the Create Instance section of the EC2 dashboard.
- 3. Select the AMI for your Cloudera Director instance. Cloudera recommends that you choose from the Community AMIs list and the latest release of the desired supported distribution. See Supported Software and Distributions on page 43.
  - **a.** Select **Community AMIs** in the left pane.
  - b. In the search box, type the desired operating system. For example, if you type rhel-7.3 HVM, the search results show the versions of RHEL v7.3 that support HVM. Select the highest GA number to use the latest release of RHEL v7.3 supporting HVM.

#### Step 1: Choose an Amazon Machine Image (AMI) An AMI is a template that contains the software configuration (operating system, application server, and applications) required to launch your instance. You can select an AMI provided by AWS, our user community, or the AWS Marketplace; or you can select one of your own AMIs.

**c.** Click **Select** for the AMI version you choose.

**Note:** For more information on finding AMIs, see Choosing an AMI. l d

- 4. Select the instance type for Cloudera Director. Cloudera recommends using c3.large or c4.large instances.
- 5. Click Next: Configure Instance Details.
  - a. Select the correct VPC and subnet.
  - b. The cluster launcher requires Internet access; from the Auto-assign Public IP list box, select Enable.
  - c. Use the default shutdown behavior, **Stop**.
  - d. Click the Protect against accidental termination checkbox.
  - e. (Optional) Click the IAM role drop-down list and select an IAM role.
- 6. Click Next: Add Storage. Cloudera Director requires a minimum of 8 GB.
- 7. Click Next: Add Tags. On the Add Tags page, click the Add Tag button. For the Name key, enter a name for the instance in the Value field. Optionally, click Add Tag again to create an additional tags for the instance (up to a maximum of 50 tags).

# Getting Started with Cloudera Director

#### Step 5: Add Tags

A tag consists of a case-sensitive key-value pair. For example, you could define a tag with key = Name and value = Webserver. A copy of a tag can be applied to volumes, instances or both.

Tags will be applied to all instances and volumes. Learn more about tagging your Amazon EC2 resources.

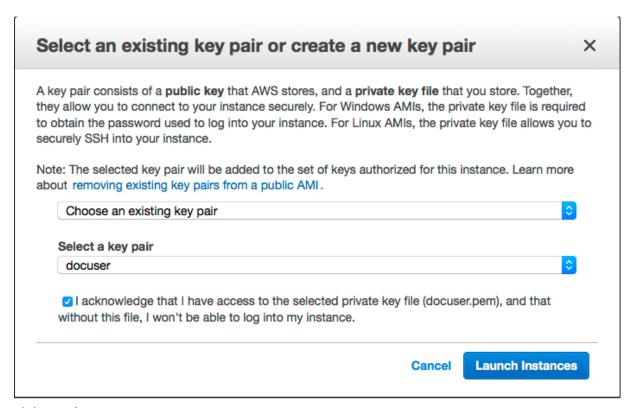

- 8. Click Next: Configure Security Group.
- 9. On the Configure Security Group page, create a new security group or add ports to an existing group. (If you have already created a security group with the required ports for Cloudera Director, as described on the previous page <u>Setting up the AWS Environment</u>, you can skip this step.)
  - a. Select either Create a new security group or Select an existing security group. If you create a new group, enter a Security group name and Description. To edit an existing group, select the group you want to edit.
  - b. Click the Type drop-down list, and select a protocol type. Type the port number in the Port Range field.
  - c. For each additional port needed, click the Add Rule button. Then click the Type drop-down list, select a protocol type, and type the port number in the **Port Range** field.

The following ports must be open for the Cloudera Director EC2 instance:

Туре	Protocol	Port Range	Source
SSH (22)	TCP (6)	22	<your address="" ip=""></your>
ALL Traffic	ALL	ALL	security_group_id

- 10 Click Review and Launch. Scroll down to review the AMI details, instance type, and security group information, and then click Launch.
- **11.** At the prompt for a key pair:
  - a. Select Choose an existing key pair and select the key pair you created in Setting up the AWS Environment on page 47.
  - **b.** Click the check box to acknowledge that you have access to the private key.

#### 12 Click Launch Instances.

**13** After the instance is created, note its public and private IP addresses.

You are now ready to install Cloudera Director server and client on the EC2 instance.

# Choosing an AMI

An Amazon Machine Image (AMI) specifies the operating system, architecture (32-bit or 64-bit), AWS Region, and virtualization type (Paravirtualization or HVM) for a virtual machine (also known as an instance) that you launch in AWS.

Important: Cloudera Director, CDH, and Cloudera Manager support only 64-bit Linux. For CDH and Cloudera Manager on Amazon EC2, Cloudera Director only supports RHEL and CentOS.

The virtualization type depends on the instance type that you use. After selecting an instance type based on the expected storage and computational load, check the supported virtualization types. Then, identify the correct AMI based on <u>architecture</u>, <u>AWS Region</u>, and <u>virtualization type</u>.

Important: Cloudera Director supports only MBR and GPT partitions for AMIs that have a single partition on the root block device. AMIs with multiple partitions are not supported.

#### Finding Available AMIs

There are two ways of finding available AMIs:

- Using the <u>AWS Management Console</u>.
- By generating a list of AMIs using the AWS CLI.

To generate a list of RHEL 64-bit AMIs using the AWS CLI, perform the following steps:

1. Install the AWS CLI.

\$ sudo pip install awscli

# Getting Started with Cloudera Director

2. Configure the AWS CLI.

```
$ aws configure
```

Follow the prompts. Choose any output format. The following example command defines "table" as the

**3.** Run the following query:

```
aws ec2 describe-images \
  --output table \
  --query 'Images[*].[VirtualizationType,Name,ImageId]' \
  --owners 309956199498 \
  --filters \
    Name=root-device-type, Values=ebs \
    Name=image-type, Values=machine \
    Name=is-public, Values=true \
    Name=hypervisor, Values=xen \
    Name=architecture, Values=x86_64
```

AWS returns a table of available images in the region you configured.

# Installing Cloudera Director Server and Client on the EC2 Instance

To install Cloudera Director, perform the following tasks. You must be either running as root or using sudo to perform these tasks.

Note: Cloudera strongly recommends using MySQL for production deployments of Cloudera Director, instead of H2. Use of the H2 database in production environments can result in excessive space consumption for database files and slow database access.

#### RHEL 7 and CentOS 7

1. SSH as ec2-user (RHEL) or centos (CentOS) into the EC2 instance you created for Cloudera Director. If you have VPN or AWS Direct Connect, SSH to your private IP address. Otherwise, use your public IP address.

ssh -i your\_file.pem ec2-user@private\_IP\_address

Note: Depending on the operating system, different AMIs may require different SSH logins. To check the SSH login name for your EC2 instance, go to the **Instances** page in the AWS Console and click the instance name to display details for your instance and click the Usage Instructions tab. In this example, centos is used, not ec2-user:

2. Install a supported version of the Oracle Java Development Kit (JDK) on the Cloudera Director host. Currently, Cloudera Director supports JDK versions 7 and 8. For download and installation information, see <u>Java SE Downloads</u> on the Oracle web site. After downloading the RPM file to the EC2 instance, install the JDK:

sudo yum localinstall jdk-version-linux-x64.rpm

3. Some RHEL 7 AMIs do not include wget by default. If your RHEL AMI does not include wget, install it now:

sudo yum install wget

**4.** Add the Cloudera Director repository to the package manager:

cd /etc/yum.repos.d/ sudo wget "https://archive.cloudera.com/director/redhat/7/x86\_64/director/cloudera-director.repo"

5. Install Cloudera Director server and client by running the following command:

sudo yum install cloudera-director-server cloudera-director-client

**6.** Start the Cloudera Director server by running the following command:

sudo service cloudera-director-server start

7. If the RHEL 7 or CentOS firewall is running on the EC2 instance where you have installed Cloudera Director, disable and stop the firewall with the following commands:

sudo systemctl disable firewalld sudo systemctl stop firewalld

You are now ready to configure a SOCKS proxy.

#### RHEL 6 and CentOS 6

1. SSH as ec2-user into the EC2 instance you created for Cloudera Director. If you have VPN or AWS Direct Connect, SSH to your private IP address. Otherwise, use your public IP address.

ssh -i your\_file.pem ec2-user@private\_IP\_address

2. Install a supported version of the Oracle Java Development Kit (JDK) on the Cloudera Director host. Currently, Cloudera Director supports JDK versions 7 and 8.

Note: Spark 2.2 requires JDK 8 and Python 2.7 or higher. For information on using Java 8 with Cloudera Director, see Deploying a Java 8 Cluster.

For download and installation information, see <u>Java SE Downloads</u>. After downloading the RPM file to the EC2 instance, install the JDK:

sudo yum localinstall jdk-version-linux-x64.rpm

**3.** Add the Cloudera Director repository to the package manager:

cd /etc/yum.repos.d/ sudo wget "https://archive.cloudera.com/director/redhat/6/x86\_64/director/cloudera-director.repo"

**4.** Install Cloudera Director server and client by running the following command:

sudo yum install cloudera-director-server cloudera-director-client

**5.** Start the Cloudera Director server by running the following command:

sudo service cloudera-director-server start

# Getting Started with Cloudera Director

6. Save the existing iptables rule set and disable the firewall:

```
sudo service iptables save
sudo chkconfig iptables off
sudo service iptables stop
```

You are now ready to configure a SOCKS proxy.

#### Ubuntu

1. SSH as ubuntu into the EC2 instance you created for Cloudera Director. If you have VPN or AWS Direct Connect, SSH to your private IP address. Otherwise use your public IP address.

```
ssh -i your_file.pem ubuntu@private_IP_address
```

2. Add the Cloudera Director repository to the package manager:

```
cd /etc/apt/sources.list.d/
sudo curl "https://archive.cloudera.com/director/ubuntu/trusty/amd64/director/cloudera-director.list" -0
```

**3.** Add the signing key:

```
sudo curl -s "https://archive.cloudera.com/director/ubuntu/trusty/amd64/director/archive.key" | sudo apt-key add
```

4. Install a supported version of the Oracle Java Development Kit (JDK) on the Cloudera Director host. Currently, Cloudera Director supports JDK versions 7 and 8. For JDK download and installation information, see Java SE <u>Downloads</u>. After downloading the installation file to the EC2 instance, install the JDK. The following example installs JDK version 7:

```
sudo apt-get update
sudo apt-get install oracle-j2sdk1.7
```

**5.** Install Cloudera Director server by running the following command:

```
sudo apt-get update
sudo apt-get install cloudera-director-server cloudera-director-client
```

**6.** Start the Cloudera Director server by running the following command:

```
sudo service cloudera-director-server start
```

**7.** Save the existing firewall rules and disable the firewall:

```
sudo iptables-save > ~/firewall.rules
sudo service ufw stop
```

You are now ready to configure a SOCKS proxy.

# Installing Only Cloudera Director Server or Cloudera Director Client

The installation instructions above will install both the server and client. Cloudera recommends installing both because together they provide the full functionality of Cloudera Director. Optionally, you can install just the client, but this will only enable you to use the client in standalone mode. Similarly, you can install just the server, but then you will be unable to launch a cluster at the command line with a customized configuration file.

To install only Cloudera Director client, run one of the following installation commands in place of the command given above:

• For RHEL and CentoOS, run the command sudo yum install cloudera-director-client instead of sudo yum install cloudera-director-server cloudera-director-client.

 For Ubuntu: run the command sudo apt-get install cloudera-director-client instead of sudo apt-get install cloudera-director-server cloudera-director-client.

To install only Cloudera Director server, run one of the following installation commands in place of the command given above:

- For RHEL and CentoOS, run the command sudo yum install cloudera-director-server instead of sudo yum install cloudera-director-server cloudera-director-client.
- For Ubuntu: run the command sudo apt-get install cloudera-director-server instead of sudo apt-get install cloudera-director-server cloudera-director-client.

# Configuring a SOCKS Proxy for Amazon EC2

In AWS, the security group that you create and specify for your EC2 instances functions as a firewall to prevent unwanted access to your cluster and Cloudera Manager. For security, Cloudera recommends that you not configure security groups to allow internet access to your instances on the instances' public IP addresses. Instead, connect to your cluster and to Cloudera Manager using a SOCKS proxy server. A SOCKS proxy server allows a client (such as your web browser) to connect directly and securely to a server (such as your Cloudera Director server web UI) and, from there, to the web UIs on other IP addresses and ports in the same subnet, including the Cloudera Manager and Hue web UIs. The SOCKS proxy provides you with access to the Cloudera Director UI, Cloudera Manager UI, Hue UI, and any other cluster web UIs without exposing their ports outside the subnet.

Note: The same result could be achieved by configuring an SSH tunnel from your browser to the EC2 instance. But an SSH tunnel enables traffic from a single client (IP address and port) to a single server (IP address and port), so this approach would require you to configure a separate SSH tunnel for each connection.

To set up a SOCKS proxy for your web browser, follow the steps below.

#### Step 1: Set Up a SOCKS Proxy Server with SSH

Set up a SOCKS proxy server with SSH to access the EC2 instance running Cloudera Director. For example, run the following command (with your instance information):

```
nohup ssh -i
        "your-key-file.pem" -CND 8157
        ec2-user@instance_running_director_server &
```

#### where

- nohup (optional) is a POSIX command to ignore the HUP (hangup) signal so that the proxy process is not terminated automatically if the terminal process is later terminated.
- your-key-file.pem is the private key you used to create the EC2 instance where Cloudera Director is running.
- C sets up compression.
- N suppresses any command execution once established.
- D 8157 sets up the SOCKS 5 proxy on the port. (The port number 8157 in this example is arbitrary, but must match the port number you specify in your browser configuration in the next step.)
- ec2-user is the AMI username for the EC2 instance where Cloudera Director is running. The AMI username can be found in the details for the instance displayed in the AWS Management Console on the Instances page under the Usage Instructions tab.
- instance\_running\_director\_server is the private IP address of the EC2 instance running Cloudera Director server, if your networking configuration provides access to it, or its public IP address if not.
- & (optional) causes the SSH connection to run as an operating system background process, independent of the command shell. (Without the  $\alpha$ , you leave your terminal open while the proxy server is running and use another terminal window to issue other commands.)

Important: If you are using a PAC file, the port specified in the PAC file must match the port used in the ssh command (port 8157 in the example above).

# Step 2: Configure Your Browser to Use the Proxy On Google Chrome

By default, Google Chrome uses system-wide proxy settings on a per-profile basis. To get around that you can start Chrome using the command line and specify the following:

- The SOCKS proxy port to use (must be the same value used in step 1)
- The profile to use (this example creates a new profile)

This creates a new profile and launches a new instance of Chrome that does not interfere with any currently running instance.

#### Linux

```
/usr/bin/google-chrome \
--user-data-dir="$HOME/chrome-with-proxy" \
--proxy-server="socks5://localhost:8157"
```

#### Mac OS X

```
"/Applications/Google Chrome.app/Contents/MacOS/Google Chrome" \
--user-data-dir="$HOME/chrome-with-proxy"
--proxy-server="socks5://localhost:8157
```

#### Microsoft Windows

```
"C:\Program Files (x86)\Google\Chrome\Application\chrome.exe" ^
--user-data-dir="%USERPROFILE%\chrome-with-proxy"
--proxy-server="socks5://localhost:8157"
```

Now in this Chrome session, you can connect to any Cloudera Director-accessible host using the private IP address or internal fully qualified domain name (FQDN). For example, when you connect to the Cloudera Director server, Cloudera Manager server, or Hue UI server, the browser actually connects to the proxy server, which performs the SSH tunneling.

#### Setting Up SwitchyOmega on the Google Chrome Browser

If you use Google Chrome, and especially if you use multiple proxies, the SwitchyOmega browser extension is a convenient tool to configure and manage all of your proxies in one place and switch from one proxy to another.

- 1. Open Google Chrome and go to <a href="Chrome Extensions">Chrome Extensions</a>.
- 2. Search for Proxy SwitchyOmega and add to it Chrome.
- 3. In the Profiles menu of the SwitchyOmega Options screen, click New profile and do the following:
  - a. In the Profile Name field, enter AWS-Cloudera.
  - b. Select the type PAC Profile.
  - c. The proxy autoconfig (PAC) script contains the rules required for Cloudera Director. Enter or copy the following into the **PAC Script** field:

```
function regExpMatch(url, pattern) {
  try { return new RegExp(pattern).test(url); } catch(ex) { return false; }
function FindProxyForURL(url, host) {
     // Important: replace 172.31 below with the proper prefix for your VPC subnet
     if (shExpMatch(url, "*172.31.*")) return "SOCKS5 localhost:8157";
if (shExpMatch(url, "*ec2*.amazonaws.com*")) return 'SOCKS5 localhost:8157';
if (shExpMatch(url, "*.compute.internal*") || shExpMatch(url,
"*://compute.internal*")) return 'SOCKS5 localhost:8157';
     if (shExpMatch(url, "*ec2.internal*")) return 'SOCKS5 localhost:8157';
```

return 'DIRECT'; }

Note: If you copy the function above, be sure to replace 172.31 with the proper prefix value for your VPC subnet.

- 4. In the Actions menu, click Apply Changes.
- **5.** On the Chrome toolbar, select the **AWS-Cloudera** profile for SwitchyOmega.

You are now ready to deploy Cloudera Manager and CDH.

# Deploying Cloudera Manager and CDH on AWS

To deploy Cloudera Manager and CDH on an AWS EC2 instance, begin by creating an environment. The environment defines common settings, like region and key pair, that Cloudera Director uses with AWS. While creating an environment, you are also prompted to deploy its first cluster.

Note: The lifecycle of instances and clusters depends on the availability of external repositories (for example, the Cloudera Manager repository). If these repositories are unreachable during this lifecycle, Cloudera Director cannot grow the cluster, and a grow operation results in a Modify failed state until the repository is available again. To ensure that there is no point of failure during cluster growth, you can preload the AMIs you use with Cloudera Manager and CDH. For more information, see Using Custom Repositories with Cloudera Manager and CDH on page 194.

# To create an environment:

1. Open a web browser and go to the private IP address of the instance you created in Launching an EC2 Instance for Cloudera Director on page 48. Include port 7189 in the address. For example:

http://192.0.2.0:7189

- 2. In the Cloudera Director login screen, enter admin in both the Username and the Password fields.
- 3. In the Cloudera Director Welcome screen, click Let's get started.

This opens a wizard for adding an environment, Cloudera Manager, and a CDH cluster.

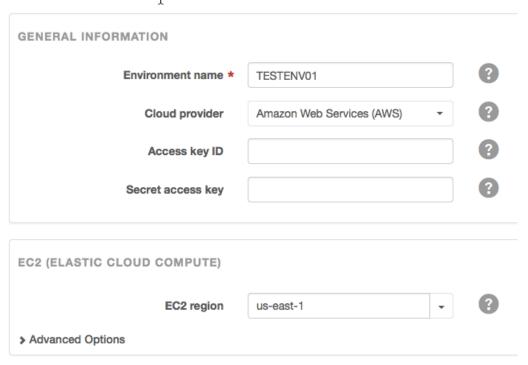

- 4. In the Add Environment screen:
  - a. Enter a name in the **Environment Name** field.
  - b. Select Amazon Web Services (AWS) from the Cloud provider field.
  - c. Enter your AWS credentials in the Access key ID and Secret access key fields.

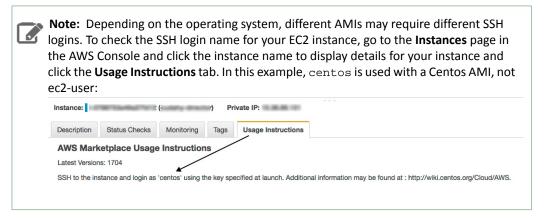

Note: Leave the Access key ID and Secret access key fields blank if you are using AWS Identity and Access Management (IAM) for authentication and authorization.

d. In the EC2 region field, select the same region in which your Cloudera Director instance was created.

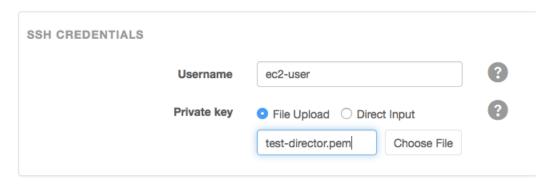

# Add Environment

- e. In the SSH Credentials section:
  - a. For a RHEL AMI, enter ec2-user in the Username field.

b. Copy the SSH private key you created in Launching an EC2 Instance for Cloudera Director on page 48 in the Private key field.

- **5.** Click **Continue** to add Cloudera Manager.
- 6. In the Add Cloudera Manager screen:
  - a. Enter a name for this deployment of Cloudera Manager in the Cloudera Manager name field.
  - b. In the Instance Template field, click Select a Template if you already have one that you want to use, otherwise, click Create New Instance Template.

The Create New Instance Template modal screen displays.

- **7.** In the **Create New Instance Template** modal screen:
  - **a.** In the **Instance Template name** field, enter a name for the template.
  - **b.** In the **Instance type** field, select **m4.large** or **m4.xlarge**.
  - c. In the Image (AMI) ID field, enter the ID for the Amazon machine image (AMI) you chose in Launching an EC2 Instance for Cloudera Director on page 48, or find another AMI with a supported operating system.

Note: To reduce cluster bootstrap times, you can preload the AMIs you use with Cloudera Manager and CDH. For more information, see <u>Using Custom Repositories with Cloudera</u> Manager and CDH on page 194.

**d.** In the **Tags** field, add one or more tags to associate with the instance.

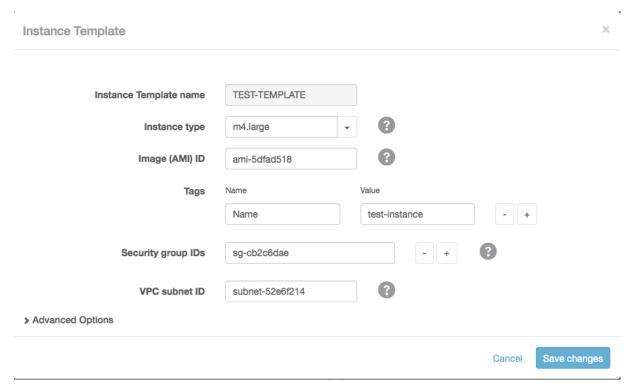

Note: Cloudera Director uses the Name field on AWS. By default, Cloudera Director puts the following values in the Name field: Cloudera Director id, Cloudera Director template name. If you want to create a custom key value for this field in place of "Name," see Configuring Cloudera Director to Use Custom Tag Names on AWS.

- e. In the Security group IDs field, enter the security group ID you set up in Creating a New Security Group on page 48.
- f. In the VPC subnet ID field, enter the ID of the VPC subnet that was created during VPC setup.
- g. Click Advanced Options if you want to specify additional values for optional features, such as EBS, IAM, Spot instances, and AWS user data.

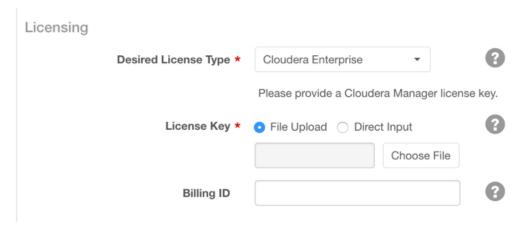

Note: With Cloudera Director 2.4 and higher, you can enter opaque data or scripts in the User data field of the instance template, and this data will be passed to the instances as they are launched, using the EC2 user data mechanism. Note that AWS requires user data to be base64-encoded. You must perform the base64-encoding manually. For more information, including examples, see Instance Metadata and User Data in the AWS documentation.

h. Click Save changes.

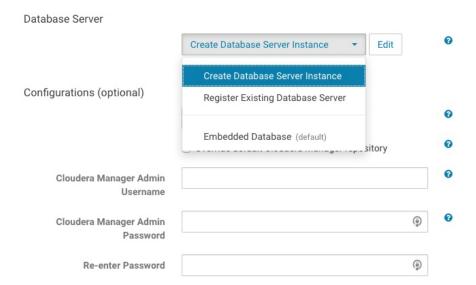

- **8.** In the **Desired License Type** field, select one of the following license types:
  - Cloudera Enterprise: includes the core CDH services (HDFS, Hive, Hue, MapReduce, Oozie, Sqoop 1, YARN, and ZooKeeper) and, depending on the license edition, one or more additional services (Accumulo, HBase, Impala, Navigator, Solr, Spark). For more information on Cloudera Enterprise licenses, see Managing Licenses in the Cloudera Manager documentation.
  - Cloudera Enterprise Trial: a 60-day trial license that includes all CDH services.
  - Cloudera Express: no license required.

To enable usage-based billing, you must have a Cloudera Enterprise license and a billing ID provided by Cloudera. Perform these steps in the **Add Cloudera Manager** screen:

- 1. In the Desired License Type field, select Cloudera Enterprise.
- 2. In the License Key field, either select a Cloudera Enterprise license file to upload or select Direct Input and input the license file text directly into the text area.
- 3. To enable usage-based billing, enter the billing ID provided to you by Cloudera in the Billing ID field.
- 9. In the Database Server section, the default selection is Embedded Database. This installs an embedded PostgreSQL database for Cloudera Manager. The embedded PostgreSQL database should be used only when creating a demonstration or proof-of-concept deployment. It is not recommended for production. If desired, select Create

# Database Server Instance or Register Existing Database Server from the dropdown list, instead of Embedded Database:

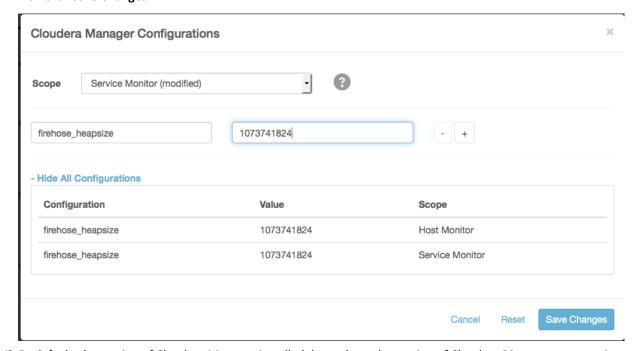

For information about using an external database for Cloudera Director server, see the following pages:

- Using MySQL for Cloudera Director Server on page 115
- Using MariaDB for Cloudera Director Server on page 128

10 In the Add Cloudera Manager screen, click Cloudera Manager Configurations.

11 In the Cloudera Manager Configurations modal screen, set the heap size:

- a. In the Scope field, select Host Monitor and add firehose\_heapsize and 1073741824 in the respective Name and Value fields.
- b. Click +.
- c. In the Scope field, select Service Monitor and add firehose\_heapsize and 1073741824 in the respective Name and Value fields.
- d. Click Save Changes.

12 By default, the version of Cloudera Manager installed depends on the version of Cloudera Director you are using:

Cloudera Director version	Cloudera Manager version installed
Cloudera Director 2.0	Latest released version of Cloudera Manager 5.5
Cloudera Director 2.1	Latest released version of Cloudera Manager 5.7
Cloudera Director 2.2	Latest released version of Cloudera Manager 5.8
Cloudera Director 2.3	Latest released version of Cloudera Manager 5.10
Cloudera Director 2.4	Latest released version of Cloudera Manager 5.11
Cloudera Director 2.5	Latest released version of Cloudera Manager 5.12
Cloudera Director 2.6	Latest released version of Cloudera Manager 5.13

To install a version of Cloudera Manager higher or lower than the default version, perform the following steps:

- a. In the Configurations section, check Override default Cloudera Manager repository.
- b. In the Repository URL field, enter the repository URL for the version of Cloudera Manager to install. Repository URLs for versions of Cloudera Manager 5 have the form <a href="https://archive.cloudera.com/cm5/">https://archive.cloudera.com/cm5/</a> followed by the operating system, operating system major version, processor architecture, cm (for Cloudera Manager), and the Cloudera Manager major, minor, and (if applicable) maintenance release number. For example, the repository URL for Cloudera Manager 5.5.4 on any supported version of RHEL 7 is https://archive.cloudera.com/cm5/redhat/7/x86 64/cm/5.5.4/.

Note: The Cloudera Manager minor version must the same as or higher than the CDH minor version. For example, Cloudera Manager 5.5 cannot be used to launch or manage a CDH 5.7 cluster, but Cloudera Manager 5.7 can be used with a CDH 5.7 (or lower) cluster.

- c. In the Repository Key URL field, enter the URL for the repository key. Repository key URLs have the same form as repository URLs except they end with the name of the key file instead of the Cloudera Manager version. For example, the repository key URL for any version of Cloudera Manager 5 on any supported version of RHEL 7 is https://archive.cloudera.com/cm5/redhat/7/x86 64/cm/RPM-GPG-KEY-cloudera.
- 13 In the Add Cloudera Manager screen, click Continue.
- **14** At the **Confirmation** prompt, click **OK** to begin adding a cluster.
- 15 On the Add Cluster screen:
  - a. Enter a name for the cluster in the Cluster name field.
  - b. Enter the version of CDH to deploy in the Version field or leave the default value. By default, the version of CDH installed depends on the version of Cloudera Director you are using:

Cloudera Director version	CDH version installed
Cloudera Director 2.0	Latest released version of CDH 5.5
Cloudera Director 2.1	Latest released version of CDH 5.7
Cloudera Director 2.2	Latest released version of CDH 5.9
Cloudera Director 2.3	Latest released version of CDH 5.10
Cloudera Director 2.4	Latest released version of CDH 5.11
Cloudera Director 2.5	Latest released version of CDH 5.12
Cloudera Director 2.6	Latest released version of CDH 5.13

To install a version of CDH higher or lower than the default version, perform the following steps:

a. Enter the desired CDH version in the Version field of the Products section. For example, for CDH 5.4.8 enter 5.4.8.

- **b.** Scroll down to **Configurations (optional)** and expand the section.
- c. Click Override default parcel repositories.
- d. Enter the repository parcel URL for the version of CDH you want to install. Parcel URLs for versions of CDH 5 have the form https://archive.cloudera.com/cdh5/parcels/, followed by the major, minor, and (if applicable) maintenance release number. For example, the URL for CDH 5.4.8 is https://archive.cloudera.com/cdh5/parcels/5.4.8.

Note: The CDH minor version must not be higher than the Cloudera Manager minor version. For example, CDH 5.7 will not work with Cloudera Manager 5.5, but CDH 5.7 (or lower) will work with Cloudera Manager 5.7.

- **c.** In the **Services** section, select the services you want to install.
- d. In the Instance groups area, choose an existing instance template or create a new one, either for the all instance groups in the cluster, or for each group. For each instance group, indicate the number of instances you want.

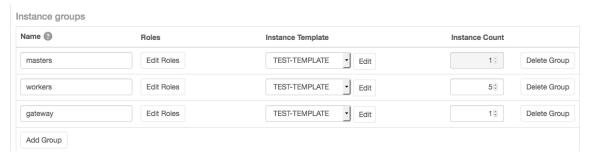

Note: To reduce cluster bootstrap times, you can preload the AMIs you use for your cluster instance groups. For more information, see <u>Using Custom Repositories with Cloudera Manager</u> and CDH on page 194.

If you want to use Spot instances for your workers group:

- a. In the Create New Instance Template modal screen, click Advanced Options.
- **b.** In the **Spot bid (USD/hr)** field, enter your Spot bid price.
- c. Click the Use Spot instances checkbox.
- d. Click Save Changes.

For more information about using Spot instances with Cloudera Director, see Using Spot Instances on page 203.

- 16 Click Continue.
- 17. At the Confirmation prompt, click OK to deploy the cluster. Cloudera Director displays a status screen.

#### **Status**

**18** When the cluster is ready, click **Continue**.

You are finished with the deployment tasks.

# Pausing a Cluster in AWS

If all data for a cluster is stored on EBS volumes, you can pause the cluster and stop your AWS EC2 instances during periods when the cluster will not be used. The cluster will not be available while paused and can't be used to ingest or process data, but you won't be billed by Amazon for the stopped EC2 instances. Provisioned EBS storage volumes will continue to accrue charges.

**Important:** Pausing a cluster requires using EBS volumes for all storage, both on management and worker nodes. Data stored on ephemeral disks will be lost after EC2 instances are stopped.

# Shutting Down and Starting Up the Cluster

In the shutdown and startup procedures below, some steps are performed in the AWS console and some are performed in Cloudera Manager:

- For AWS actions, use one of the following interfaces:
  - AWS console
  - AWS CLI
  - AWS API
- For cluster actions, use one of the following interfaces:
  - The Cloudera Manager web UI
  - The Cloudera API start and stop commands

#### Shutdown procedure

To pause the cluster, take the following steps:

- 1. Stop the cluster (in Cloudera Manager).
- 2. Stop the Cloudera Management Service (in Cloudera Manager).
- 3. Stop all cluster EC2 instances, including the Cloudera Manager host (in AWS).

#### Startup procedure

To restart the cluster after a pause, the steps are reversed:

- 1. Start all cluster EC2 instances (in AWS).
- 2. Start the Cloudera Management Service (in Cloudera Manager).
- 3. Start the cluster (in Cloudera Manager).

#### More information

For more information about stopping the Cloudera Management Service, see Stopping the Cloudera Management Service in the Cloudera Enterprise documentation.

For more information about restarting the Cloudera Management Service, see Restarting the Cloudera Management Service in the Cloudera Enterprise documentation.

For more information about starting and stopping a cluster in Cloudera Manager, see Starting, Stopping, Refreshing, and Restarting a Cluster in the Cloudera Enterprise documentation.

For more information about stopping and starting EC2 instances, see Stop and Start Your Instance in the AWS documentation.

#### Considerations after Restart

Since the cluster was completely stopped before stopping the EC2 instances, the cluster should be healthy upon restart and ready for use. You should be aware of the following about the restarted cluster:

 After starting the EC2 instances, Cloudera Manager and its agents will be running but the cluster will be stopped. There will be gaps in Cloudera Manager's time-based metrics and charts.

 EC2 instances retain their internal IP address and hostname for their lifetime, so no reconfiguration of CDH is required after restart. The public IP and DNS hostnames, however, will be different. Elastic IPs can be configured to remain associated with a stopped instance at additional cost, but it isn't necessary to maintain proper cluster operation.

# Cleaning Up Your AWS Deployment

When you are done testing or using Cloudera Director, terminate your instances to stop incurring charges to your AWS account.

- 1. In Cloudera Director, terminate each instance in your clusters.
  - a. Click an environment name.
  - **b.** In the **Actions** column, select **Terminate Cluster**.
  - c. Repeat for each environment you configured.
- 2. If you want to save anything in Cloudera Director (the configuration file or database, for example), back it up.
- 3. In the AWS Management Console, terminate the Cloudera Director instance and any other instance Cloudera Director was unable to terminate.
- 4. If applicable, terminate any external database you configured Cloudera Director to use.

# Getting Started on Google Cloud Platform

To use Cloudera Director on Google Cloud Platform, you create a project, start an instance in Google Compute to run Cloudera Director, and create a secure connection. This section details steps for each of these tasks.

**Important:** Cloudera Director supports preemptible virtual machines. Preemptible virtual machines are short-lived instances that have a lower cost but are subject to reclamation at any time by Google Compute Engine. Because of the possibility of interruption, we recommend that you use preemptible virtual machines only for worker roles in a cluster, not for master or gateway roles. For more information, see the Google Cloud Platform's Preemptible Virtual Machines page.

# Creating a Google Cloud Platform Project

To run Cloudera Director on Google Cloud Platform, begin by creating a project:

- 1. Go to the Google Cloud Platform web site.
- **2.** Click **My console** in the upper-right corner of the screen.
- 3. Select your Google account, and sign in.

Your screen is redirected to the **Google Developers Console**.

- 4. In the Google Developers Console, click Select a project > Create a project.
- 5. In the New Project form, enter a project name, click that you agree to the terms of service, and click Create.

Note: To create a project in Google Cloud Platform, first create a billing account or a free trial account, or sign into an existing billing account. To create an account, click **Create new billing account** in the Google Developers Console.

You are ready to configure tools for your project.

# Configuring Tools for Your Google Cloud Platform Account

Before installing Cloudera Director, Cloudera recommends that you configure some tools for your Google Cloud Platform account.

Create a service account for Cloudera Director.

# Getting Started with Cloudera Director

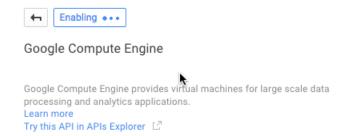

- 2. Create an SSH key.
- 3. Set up gcloud compute.

#### Creating a Service Account for Cloudera Director

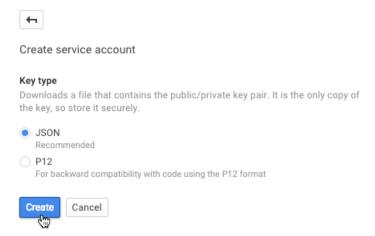

A service account enables Cloudera Director to authenticate to various Google Cloud Platform services, such as Google Cloud Storage. To create a service account, perform the following steps:

- 1. Ensure that the Google Compute Engine API is enabled. In the Google Cloud Platform console for your project, click API Manager.
- 2. Click Compute Engine API (under Google Cloud APIs).
- 3. If not already enabled, click Enable API.
- 4. At the prompt, click Enable Billing.
- **5.** At the prompt, select the billing account and click **Set account**.

A status displays, showing that the Google Compute Engine API is enabling.

- 6. Click API Manager...
- 7. In the API Manager menu, click Credentials.
- 8. In the Credentials screen, click New credentials > Service account key.
- 9. In the Create service account key screen, click JSON and click Create.

You are prompted to save the JSON file to your local machine. Note the location where you download this file. You will be prompted to select this file later, when you create an environment in Cloudera Director.

# Creating and Uploading an SSH Key

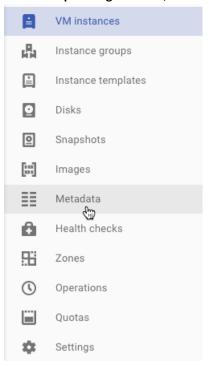

To SSH into an instance using your own terminal (as opposed to the Google Cloud Platform console), you must generate and upload an SSH key.

**1.** Generate an SSH key using the following command:

```
$ ssh-keygen -f ~/.ssh/my_gcp_keyname -t rsa
```

This generates a public/private key pair.

2. In the Compute Engine menu, click Metadata.

- 3. Click the SSH Keys tab and click Add SSH Keys.
- **4.** Copy your key data into the input box in the following format:

protocol public-key-data username@example.com

**5.** Click **Save**. Your public key is now available to all instances in the project.

# Installing gcloud compute

Cloudera recommends installing the gcloud compute command-line tool because it allows you to manage your Google Compute Engine resources more easily. To install and configure gcloud compute, follow the instructions at gcloud compute.

You are ready to create a new VM instance within your project.

# Creating a Google Compute Engine VM Instance

Once you have created or selected a project in the Google Developers Console, you can create a new VM instance in your project.

- 1. In the left side menu of the Google Developers Console, click Compute > Compute Engine > VM instances.
- 2. Click Create Instance.
- **3.** Provide the following values to define your VM instance:

**Table 2: VM Instance Values** 

Name	Description	Details/Restrictions
Name	Name of the instance.	The name must start with a lowercase letter followed by up to 62 lowercase letters, numbers, or hyphens. The name cannot end with a hyphen.

# Getting Started with Cloudera Director

Name	Description	Details/Restrictions
Zone	Where your data is stored.	Some resources can only be used by other resources in the same zone or region. For example, to attach a disk to a VM instance, both resources must reside in the same zone. For more information, see <a href="Regions and Zones">Regions and Zones</a> in the Google Cloud Platform documentation.
Machine type	The number of CPUs and amount of memory for your	Cloudera recommends a machine type of at least n1-standard-1 for this Quick Start instance.
instance.	For a production instance, Cloudera recommends at least an n1-standard-2 instance for running Cloudera Director and an n1-highmem-8 instance for running Cloudera Manager and CDH.	
Boot disk	The disk to boot from.	Select a preconfigured image with a version of Linux supported for Cloudera Director. For more information about supported Linux versions, see <a href="Supported Software">Supported Software</a> and Distributions on page 43.
Boot disk type	The type of boot disk.	For this Quick Start, choose standard persistent disk for less expensive storage space. A solid-state persistent disk (SSD) is better suited to handling high rates of random I/O operations per second (IOPS) or streaming throughput with low latency.
Firewall	Traffic to block.	Leave both HTTP and HTTPS traffic unchecked.
Project access	Access to Google Cloud services.	Leave this unchecked (disabled). These services are not used in this QuickStart.
Management, disk, networking, access & security options	Additional options available when you click the double arrows.	Use the default values for all of these settings.

You are now read to <u>install Cloudera Director Server and Client</u> on your instance.

# Installing Cloudera Director Server and Client on Google Compute Engine

Cloudera recommends that you install Cloudera Director server on your cloud provider in the subnet where you will create CDH clusters, because Cloudera Director must have access to the private IP addresses of the instances that it creates. To install Cloudera Director server, perform the following tasks.

**Note:** You must be either running as root or using sudo to perform these tasks.

# RHEL 6 and CentOS 6

1. In the Compute Engine > VM instances screen, click the SSH link next to your instance name.

This opens a new window.

Note: Alternatively, you can connect to your instance using:

• SSH in a terminal using the following command:

```
ssh -i your_key_file -o UserKnownHostsFile=/dev/null \
 -o CheckHostIP=no -o StrictHostKeyChecking=no user@ip_address
```

- The gcloud compute ssh command. When you connect to your instance for the first time using the gcloud compute command-line tool, gcloud automatically creates an SSH key and inserts it into the instance.
- 2. Install a supported version of the Oracle Java Development Kit (JDK) on the Cloudera Director host. Currently, Cloudera Director supports JDK versions 7 and 8.

Note: Spark 2.2 requires JDK 8 and Python 2.7 or higher. For information on using Java 8 with Cloudera Director, see **Deploying a Java 8 Cluster**.

For installation information, see <u>Java SE Downloads</u>.

3. Download Cloudera Director by running the following commands:

```
cd /etc/yum.repos.d/
sudo wget "https://archive.cloudera.com/director/redhat/6/x86_64/director/cloudera-director.repo"
```

**4.** Install Cloudera Director server by running the following command:

```
sudo yum install cloudera-director-server cloudera-director-client
```

5. Start the Cloudera Director server by running the following command:

```
sudo service cloudera-director-server start
```

**6.** Save the existing iptables rule set and disable the firewall:

```
sudo service iptables save
sudo chkconfig iptables off
sudo service iptables stop
```

You are now ready to configure a SOCKS proxy for your instances.

#### RHEL 7 and CentOS 7

1. In the Compute Engine > VM instances screen, click the SSH link next to your instance name.

This opens a new window.

Note: Alternatively, you can connect to your instance using:

SSH in a terminal using the following command:

```
ssh -i your_key_file -o UserKnownHostsFile=/dev/null \
 -o CheckHostIP=no -o StrictHostKeyChecking=no user@ip_address
```

The gcloud compute ssh command. When you connect to your instance for the first time using the gcloud compute command-line tool, gcloud automatically creates an ssh key and inserts it into the instance.

# Getting Started with Cloudera Director

- 2. Install a supported version of the Oracle Java Development Kit (JDK) on the Cloudera Director host. Currently, Cloudera Director supports JDK versions 7 and 8. For installation information, see Java SE Downloads.
- 3. Download Cloudera Director by running the following commands:

```
cd /etc/yum.repos.d/
```

**4.** Install Cloudera Director server by running the following command:

```
sudo yum install cloudera-director-server cloudera-director-client
```

**5.** Start the Cloudera Director server by running the following command:

```
sudo service cloudera-director-server start
```

**6.** Disable and stop the firewall with the following commands:

```
sudo systemctl disable firewalld
sudo systemctl stop firewalld
```

You are now ready to configure a SOCKS proxy for your instances.

#### Ubuntu

1. In the Compute Engine > VM instances screen, click the SSH link next to your instance name.

This opens a new window.

Note: Alternatively, you can connect to your instance using:

SSH in a terminal using the following command:

```
ssh -i your_key_file -o UserKnownHostsFile=/dev/null \
 -o CheckHostIP=no -o StrictHostKeyChecking=no user@ip_address
```

- The gcloud compute ssh command. When you connect to your instance for the first time using the gcloud compute command-line tool, gcloud automatically creates an SSH key and inserts it into the instance.
- 2. Install a supported version of the Oracle Java Development Kit (JDK) on the Cloudera Director host. Currently, Cloudera Director supports JDK versions 7 and 8. For installation information, see Java SE Downloads.
- **3.** Download Cloudera Director by running the following commands:

```
cd /etc/apt/sources.list.d/
sudo wget "https://archive.cloudera.com/director/ubuntu/trusty/amd64/director/cloudera-director.list"
```

**4.** Add the signing key by running the following command:

```
curl -s "https://archive.cloudera.com/director/ubuntu/trusty/amd64/director/archive.key"
 | sudo apt-key add -
```

**5.** Install Cloudera Director server by running the following command:

```
apt-get update
apt-get install cloudera-director-server
apt-get install oracle-j2sdk1.7
```

**6.** Start the Cloudera Director server by running the following command:

```
sudo service cloudera-director-server start
```

**7.** Save the existing firewall rules and disable the firewall:

```
iptables-save > ~/firewall.rules
sudo service ufw stop
```

You are now ready to configure a SOCKS proxy for your instances.

# Configuring a SOCKS Proxy for Google Compute Engine

For security purposes, Cloudera recommends that you connect to your cluster using a SOCKS proxy. A SOCKS proxy allows a client to connect directly and securely to a server (the Cloudera Director instance).

To set up a SOCKS proxy, follow the steps in the Google Compute Engine documentation, Securely Connecting to VM <u>Instances</u>, and follow the instructions for setting up a SOCKS proxy over SSH.

Once you have set up a SOCKS proxy, you can deploy Cloudera Manager and CDH.

# Deploying Cloudera Manager and CDH on Google Compute Engine

To deploy Cloudera Manager and CDH on an Google Compute VM instance, begin by creating an environment. The environment defines common settings, like region and key pair, that Cloudera Director uses with Google Cloud Platform. While creating an environment, you are also prompted to deploy its first cluster.

To create an environment:

1. Open a web browser and go to the private IP address of the instance you created in Creating a Google Compute <u>Engine VM Instance</u> on page 67. Include port 7189 in the address. For example:

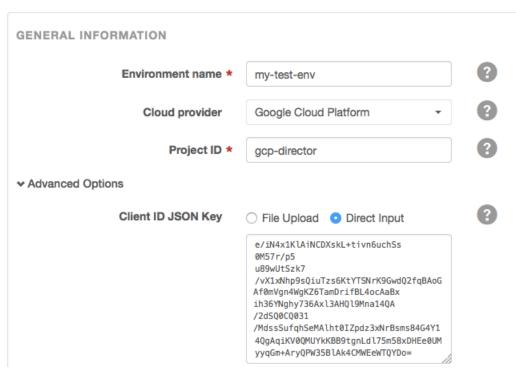

http://192.0.2.0:7189

- 2. In the Cloudera Director login screen, enter admin in both the Username and the Password fields.
- 3. In the Cloudera Director Welcome screen, click Let's get started.

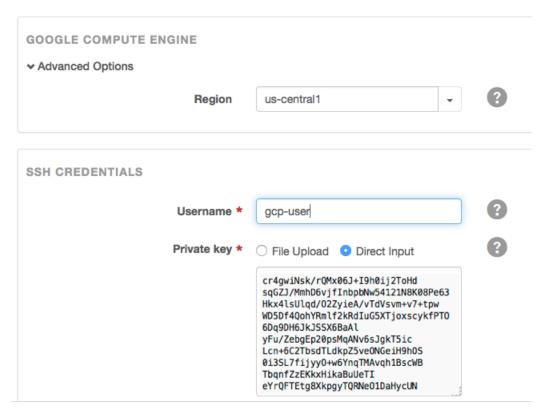

This opens a wizard for adding an environment, adding Cloudera Manager, and adding a CDH cluster.

- **4.** In the **Add Environment** screen:
  - a. Enter a name in the Environment Name field.
  - **b.** In the Cloud provider field, select Google Cloud Provider.
  - c. In the Project ID field, enter the ID for the project you created in Creating a Google Cloud Platform Project on page 65.
  - d. In the Advanced Options area, upload or copy the JSON key to the Client ID JSON Key field. You created this key in Configuring Tools for Your Google Cloud Platform Account on page 65.

# Add Environment

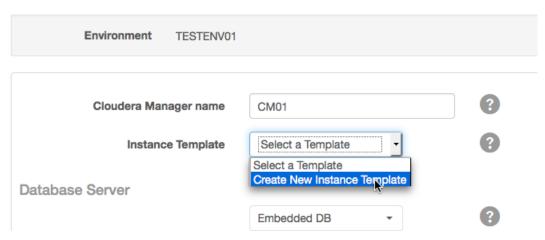

- e. In the Advanced Options section, enter the same region that your Cloudera Director instance was created
- f. In the SSH Credentials section:
  - Enter a username in the **Username** field. Google Compute will create the user specified here.
  - Copy the SSH private key you created in <u>Creating and Uploading an SSH Key</u> on page 66 in the **Private** key field.

- 5. Click Continue to add Cloudera Manager.
- **6.** In the **Add Cloudera Manager** screen:
  - Enter a name for this deployment of Cloudera Manager in the Cloudera Manager name field.
  - In the Instance Template field, select Create New Instance Template.

The Instance Template modal screen displays.

# Add Cloudera Manager

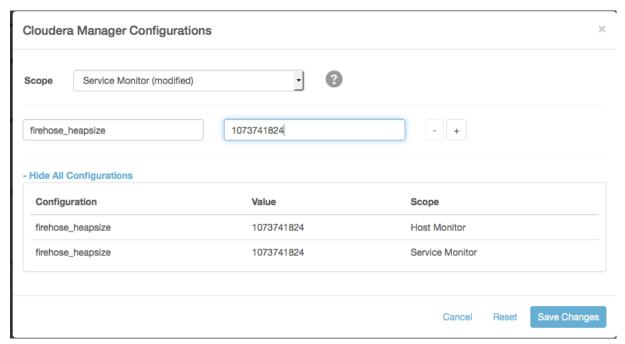

- **7.** In the **Instance Template** modal screen, do the following:
  - In the **Instance Template name** field, enter a name for the template.
  - In the Instance type field, select n1-highmem-4 or n1-highmem-8.
  - In the Machine type field, enter the machine type you chose in <u>Creating a Google Compute Engine VM</u> Instance on page 67.

- In the **Tags** field, add one or more tags to associate with the instance.
- Click Save changes.
- 8. In the Add Cloudera Manager screen, click Cloudera Manager Configurations.

The **Cloudera Manager Configurations** modal screen displays.

- **9.** In the **Cloudera Manager Configurations** modal screen, set the heap size:
  - In the **Scope** field, select **Host Monitor** and add firehose heapsize and 1073741824 in the respective Name and Value fields.
  - Click +.
  - In the Scope field, select Service Monitor and add firehose heapsize and 1073741824 in the respective Name and Value fields.
  - Click Save Changes.

10 By default, the version of Cloudera Manager installed depends on the version of Cloudera Director you are using:

Cloudera Director version	Cloudera Manager version installed	
Cloudera Director 2.0	Latest released version of Cloudera Manager 5.5	
Cloudera Director 2.1	Latest released version of Cloudera Manager 5.7	
Cloudera Director 2.2	Latest released version of Cloudera Manager 5.8	
Cloudera Director 2.3	Latest released version of Cloudera Manager 5.10	
Cloudera Director 2.4	Latest released version of Cloudera Manager 5.11	
Cloudera Director 2.5	Latest released version of Cloudera Manager 5.12	
Cloudera Director 2.6	Latest released version of Cloudera Manager 5.13	

To install a version of Cloudera Manager higher or lower than the default version, perform the following steps:

- a. In the Configurations section, check Override default Cloudera Manager repository.
- b. In the Repository URL field, enter the repository URL for the version of Cloudera Manager to install. Repository URLs for versions of Cloudera Manager 5 have the form <a href="https://archive.cloudera.com/cm5/">https://archive.cloudera.com/cm5/</a> followed by the operating system, operating system major version, processor architecture, cm (for Cloudera Manager), and

the Cloudera Manager major, minor, and (if applicable) maintenance release number. For example, for Cloudera Manager 5.5.4, the repository URL is <a href="https://archive.cloudera.com/cm5/redhat/7/x86-64/cm/5.5.4/">https://archive.cloudera.com/cm5/redhat/7/x86-64/cm/5.5.4/</a>.

Note: The Cloudera Manager minor version must the same as or higher than the CDH minor version. For example, Cloudera Manager 5.5 cannot be used to launch or manage a CDH 5.7 cluster, but Cloudera Manager 5.7 can be used with a CDH 5.7 (or lower) cluster.

- c. In the Repository Key URL field, enter the URL for the repository key. Repository key URLs have the same form as repository URLs except they end with the name of the key file instead of the Cloudera Manager version. For example, the repository key URL for any version of Cloudera Manager 5 on any supported version of Red Hat 7 is https://archive.cloudera.com/cm5/redhat/7/x86 64/cm/RPM-GPG-KEY-cloudera.
- 11 In the Add Cloudera Manager screen, click Continue.
- **12** At the **Confirmation** prompt, click **OK** to begin adding a cluster.
- 13 On the Add Cluster screen:
  - Enter a name for the cluster in the Cluster name field.
  - Enter the version of CDH to deploy in the **Version** field or leave the default value. By default, the version of CDH installed depends on the version of Cloudera Director you are using:

Cloudera Director version	CDH version installed	
Cloudera Director 2.0	Latest released version of CDH 5.5	
Cloudera Director 2.1	Latest released version of CDH 5.7	
Cloudera Director 2.2	Latest released version of CDH 5.9	
Cloudera Director 2.3	Latest released version of CDH 5.10	
Cloudera Director 2.4	Latest released version of CDH 5.11	
Cloudera Director 2.5	Latest released version of CDH 5.12	
Cloudera Director 2.6	Latest released version of CDH 5.13	

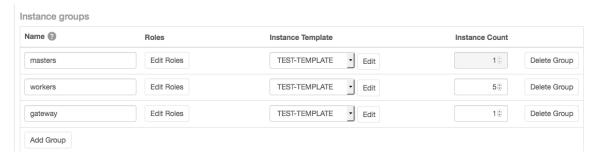

To install a version of CDH higher or lower than the default version, perform the following steps:

- 1. Enter the desired CDH version in the Version field of the Products section. For example, for CDH 5.4.8 enter 5.4.8.
- 2. Scroll down to Configurations (optional) and expand the section.
- 3. Click Override default parcel repositories.
- 4. Enter the repository parcel URL for the version of CDH you want to install. Parcel URLs for versions of CDH 5 have the form https://archive.cloudera.com/cdh5/parcels/, followed by the major, minor, and (if applicable) dot release number. For example, the URL for CDH 5.4.8 is https://archive.cloudera.com/cdh5/parcels/5.4.8.

Note: The CDH minor version must not be higher than the Cloudera Manager minor version. For example, CDH 5.7 will not work with Cloudera Manager 5.5, but CDH 5.7 (or lower) will work with Cloudera Manager 5.7.

- In the **Services** section, select the services you want to install.
- In the Instance groups area, create a new template for the groups or for each group and the number of instances you want.

#### 14 Click Continue.

15 At the Confirmation prompt, click OK to deploy the cluster. Cloudera Director displays a status screen.

### **Status**

16 When the cluster is ready, click Continue.

You are finished with the deployment tasks.

## Cleaning Up Your Google Cloud Platform Deployment

When you are done testing or using Cloudera Director, terminate your instances to stop incurring charges to your Google Cloud Platform account.

- 1. In Cloudera Director, terminate each instance in your clusters.
  - · Click an environment name.
  - In the Actions column, select Terminate Cluster.
  - Repeat for each environment you configured.
- 2. If you want to save anything in Cloudera Director (the configuration file or database, for example), back it up.
- 3. In the Google Compute Console, delete the Cloudera Director instance and any other instance Cloudera Director was unable to delete.
- 4. If applicable, delete any external database you configured Cloudera Director to use.

# **Getting Started on Microsoft Azure**

Before you can use Cloudera Director to deploy a cluster on Microsoft Azure, you must create the Azure resources the cluster requires. This section describes the resources you must create and steps for creating them.

For best practices when creating a cluster on Microsoft Azure, see Cloudera Enterprise Reference Architecture for Azure Deployments.

## **Obtaining Credentials for Cloudera Director**

To get started with Cloudera Director and Microsoft Azure, you create an Active Directory (AD) application and service principal and obtain the required Azure credentials for Director. The service principal is tied to the AD application, and Cloudera Director uses the service principal credentials to create and delete resources on Microsoft Azure.

Follow these general steps to obtain the required credentials:

- 1. Create the AD application and make sure that it has the contributor role in your Azure subscription, which allows you to create and delete resources. If you are not sure about these settings, contact your Active Directory administrator or Microsoft Azure Support.
- 2. Create the service principal. This is typically created by a system administrator or security administrator in your organization. This person must have administrator privileges for your Microsoft Azure subscription.
- **3.** Obtain the following Azure credentials for Cloudera Director:
  - Subscription ID You can get the subscription ID in the Azure Portal (either the new or old portal); see the Azure subscriptions blade.
  - Tenant ID
  - Client ID
  - Client Secret

You can create the AD application and service principal, get the tenant ID, client ID, and client secret, and assign the contributor role to the newly-created AD application by following one of these two methods:

- **1.** The <u>Azure Portal Steps</u> (easier to follow and recommended)
- 2. The Azure CLI Steps

**Note:** The *client secret* is referred to as the application *password* in the <u>Azure CLI Steps</u>

If you are having trouble finding this information, contact Microsoft support.

## Setting up Azure Resources

This topic describes how to set up various resources required by Microsoft Azure:

#### **Setting Up Resource Groups**

Cloudera Director requires you to set up resource groups that house the following cluster resources::

- Azure virtual machines (VMs)
- Azure virtual network (VNet)
- Azure network security group (NSG)

These resources typically have different lifecycles, so you may want to locate each in a separate resource group for convenience. For simplicity, you can locate them in the same resource group instead.

#### Creating a New Resource Group

To create a new resource group, perform the following steps:

- 1. In the left pane, click New.
- **2.** Type resource group in the search box.
- 3. Click Resource Group in the search result.
- 4. Click Create.
- **5.** Type in a name for the resource group.

Repeat these steps to create multiple resource groups for Azure resources.

### Setting Up a Network Security Group

This section explains how to create a new network security group (NSG) in Azure.

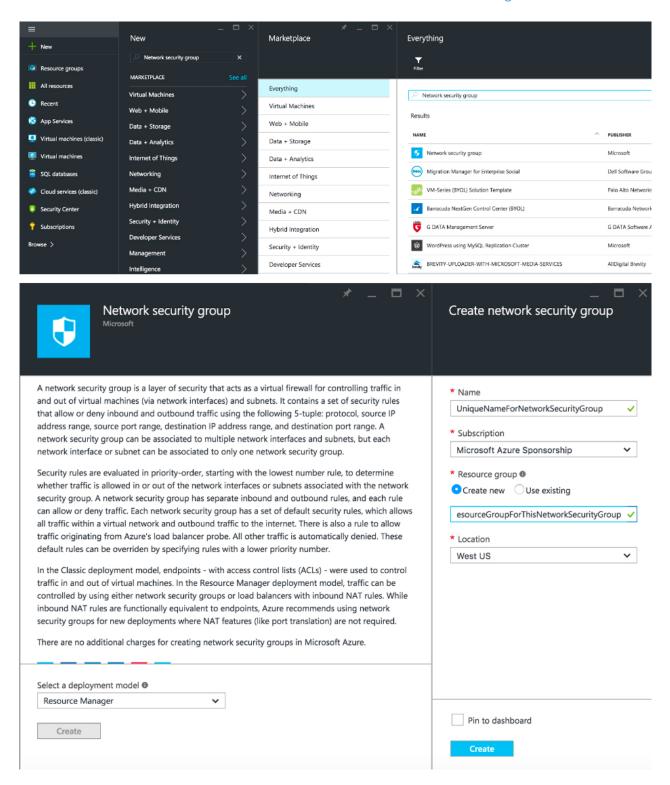

Note: You must open the following ports if you are allowing access to the web UI from public IP addresses:

- Cloudera Director 7189
- Cloudera Manager 7180

## Creating a New Network Security Group

To create a new network security group:

- 1. In the left pane, click **New**.
- **2.** Type Network security group in the search box.
- 3. Click Network security group in the search result.
- 4. Click Create.
- **5.** Type in a name for the network security group.
- **6.** Type in a name for new resource group or select an existing resource group.
- 7. Click Create.
- 8. Once created, see How to manage NSGs using the Azure portal in the Microsoft Azure documentation for instructions on creating the rules in the network security group.

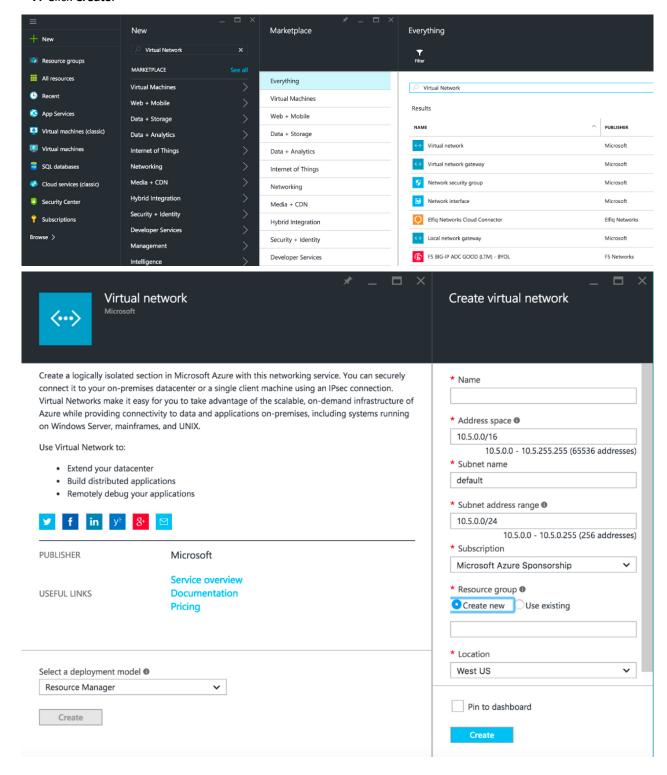

## Setting Up a Virtual Network (VNet) and Subnet

Cloudera Director requires a virtual network and subnet to implement its networking environment. The networking environment must be set up for forward and reverse hostname resolution. For a basic example for setting up forward and reverse hostname resolution, see <u>Setting Up Dynamic DNS on Azure</u> on page 82.

For an overview of virtual networks on Azure, see Virtual networks.

To set up a new virtual network and its subnets, follow the steps below. Skip these steps if you are using an existing virtual network and subnet.

- 1. In the left pane, click New.
- 2. Type Virtual Network in the search box.
- 3. Click Virtual Network in the search result.
- 4. Click Create.
- 5. Type in a name for the virtual network and subnet
- **6.** Type in a name for new resource group, or select an existing resource group.
- 7. Click Create.

#### Setting Up Availability Sets for Master Nodes and Worker Nodes

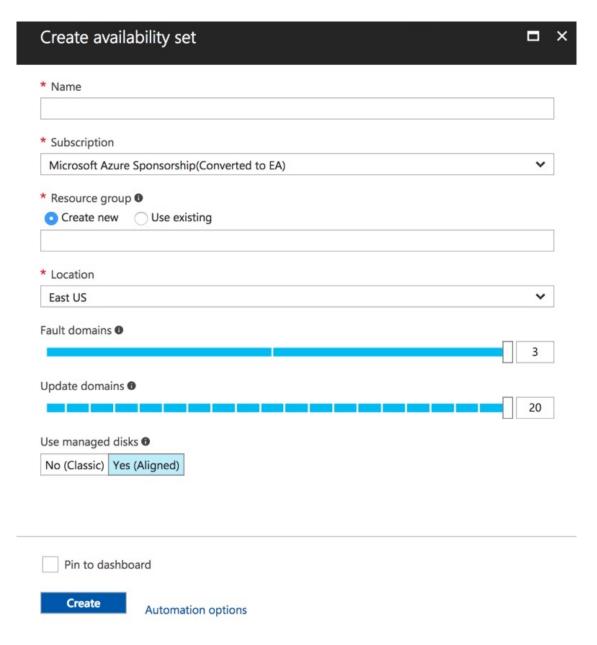

Azure uses Availability Sets to manage the availability of virtual machines. For best practices, in a CDH cluster, Cloudera recommends using one Availability Set for the master nodes and one Availability Set for the worker nodes. An Availability Set should not be shared by more than one CDH cluster.

Read this <u>Azure document</u> for an overview of Availability Sets on Azure.

To create an Availability Set:

- 1. In the left pane, click New.
- 2. Type Availability Set in the search box.
- **3.** Click **Availability Set** in the search result.
- 4. Click Create.
- **5.** Type in a name for the Availability Set.
- **6.** Type in a name for new resource group or select an existing resource group.
- **7.** Increase the fault domain and update domain to as large a size as possible.
- 8. Pick between a managed (aligned) or unmanaged (classic) Availability Set. A managed Availability Set supports the use of Managed Disks; an unmanaged Availability Set supports Unmanaged Disks in Storage Accounts. For more information on Availability Sets, see Manage the availability of Windows virtual machines in Azure in the Microsoft Azure documentation.
- 9. Click Create.

After creating the Availability Set for master nodes, repeat the steps to create an Availability Set for worker nodes.

## Setting Up Dynamic DNS on Azure

This topic describes how to set up Dynamic DNS (DDNS) on Microsoft Azure.

### Overview

Running Hadoop—specifically CDH, in this case—requires forward and reverse DNS for internal IP addresses, which is not currently supported in Microsoft Azure. You must use your own DNS server to run CDH on Azure. For more information on using your own DNS server on Azure, see Name resolution using your own DNS server in the Azure documentation. Following is basic example for setting up a DDNS server to provide forward and reverse hostname resolution.

**Important:** If you are already using your own DNS server, ensure that it supports DNS reverse lookup and skip this section.

This section provides steps for:

- · Setting up basic DDNS using BIND.
- Creating required configuration and zone files.
- Creating update scripts that automatically update BIND when IP addresses are assigned or changed (for example, when stopping and starting hosts).

Note: This document assumes certain configurations and architecture in some cases; those assumptions are noted.

#### The DNS Server and the Cloudera Director Host

#### Creating a DNS Server and Cloudera Director Host

This example shows how to set up the DNS server and Cloudera Director to run on the same host.

#### Creating a Virtual Machine for the DNS Server

- **1.** In Azure, select or create the resource group you will use for your cluster.
- **2.** Select the **+** button to add a resource within that resource group.
- 3. Search for the VM image CDH cloudera-centos and create it, following the instructions in Setting Up a Virtual Machine for Cloudera Director Server.

Make sure port 53 is accessible on the VM used for the DNS server.

## Selecting DNS Defaults

Select an internal host fully qualified domain name (FQDN) suffix. This is the suffix for all internal hostname resolution within Cloudera clusters, and is the same thing that is asked for when setting up clusters via Cloudera Director:

Host FQDN suffix ★ cdh-cluster.internal

The FQDN suffix you specify depends on your environment. Examples include cdh-cluster.internal, cluster.company-name.local, and internal.company-name.com.

Note: Cloudera provides a set of scripts on the Cloudera GitHub site to automate the BIND install and setup process. You can use the scripts with CentOS 6.7 and 7.2 and RHEL 6.7 and 7.2. These scripts are **not** intended for setting up BIND for production use.

#### Setting Up BIND on the Host

This section describes how to set up BIND on the host.

## Information from Azure

The sample BIND files use this information. Modify the values in this example for your environment.

- Hostname: director
- Virtual Network Address Space: 10.3.0.0/16
- Private IP: 10.3.0.4

### **Installing BIND**

Perform the following changes as root. Run after sudo -i, or start all commands with sudo.

```
# install bind
yum -y install bind bind-utils
# make the directories that bind will use
mkdir /etc/named/zones
# make the files that bind will use
touch /etc/named/named.conf.local
touch /etc/named/zones/db.internal
touch /etc/named/zones/db.reverse
```

## Updating or Creating the Files

The contents of each of the four files and the changes required are included below. See the comments inline for changes you need to make. You must perform the following changes as root. Run after sudo -i, or start all commands with sudo.

#### /etc/named.conf

```
// Provided by Red Hat bind package to configure the ISC BIND named(8) DNS
// server as a caching only nameserver (as a localhost DNS resolver only).
//
// See /usr/share/doc/bind*/sample/ for example named configuration files.
//
acl trusted {
    // replace `10.3.0.0/16` with your subnet
    10.3.0.0/16;
};
options {
    // replace `10.3.0.4` with the internal IP of the BIND host
    listen-on port 53 { 127.0.0.1; 10.3.0.4; };
    listen-on-v6 port 53 { ::1; };
    directory "/var/named";
    dump-file "/var/named/data/cache_dump.db";
    statistics-file "/var/named/data/named_stats.txt";
   memstatistics-file "/var/named/data/named_mem_stats.txt";
    allow-query { localhost; trusted; };
    recursion yes;
    forwarders { 168.63.129.16; }; // used for all regions
    dnssec-enable yes;
    dnssec-validation yes;
    dnssec-lookaside auto;
    /* Path to ISC DLV key */
   bindkeys-file "/etc/named.iscdlv.key";
   managed-keys-directory "/var/named/dynamic";
};
logging {
    channel default_debug {
        file "data/named.run";
        severity dynamic;
    };
};
zone "." IN {
    type hint;
    file "named.ca";
include "/etc/named.rfc1912.zones";
include "/etc/named.root.key";
include "/etc/named/named.conf.local";
```

#### /etc/named/named.conf.local

```
// replace the zone name (`cdh-cluster.internal`) with with the internal host FQDN suffix
// you want to use for your cluster network. (This option is exposed in Director.)
zone "cdh-cluster.internal" IN {
    type master;
    file "/etc/named/zones/db.internal";
    // replace with your subnet
    allow-update { 10.3.0.0/16; };
```

```
};
// replace the zone name (`0.3.10.in-addr.arpa`) with the network component of your
subnet, reversed
// (example: with a subnet definition of 10.3.0.0/24, the reversed subnet component
would be 0.3.10)
zone "0.3.10.in-addr.arpa" IN {
    type master;
    file "/etc/named/zones/db.reverse";
    // replace with your subnet
    allow-update { 10.3.0.0/16; };
 };
```

#### /etc/named/zones/db.internal

```
$ORIGIN .
$TTL 600 ; 10 minutes
; replace `cdh-cluster.internal` with the zone name defined in
/etc/named/named.conf.local)
; replace `director.cdh-cluster.internal` with the internal fqdn of the primary name
server; note the trailing period (`.`)
; replace `hostmaster.cdh-cluster.internal` with the hostmaster email address, represented
with only periods (.), by convention this is `hostmaster.<your fqdn suffix>`; note the
 trailing period (.)
cdh-cluster.internal IN SOA director.cdh-cluster.internal.
hostmaster.cdh-cluster.internal. (
        10
                  ; serial
        600
                   ; refresh (10 minutes)
        60
                   ; retry (1 minute)
        604800
                  ; expire (1 week)
        600
                   ; minimum (10 minutes)
        ; replace `director.cdh-cluster.internal` with the internal fqdn of the primary
 name server; note the trailing period (.)
        NS director.cdh-cluster.internal.
; replace `cdh-cluster.internal` with the zone name defined in
/etc/named/named.conf.local; note the trailing period (.)
$ORIGIN cdh-cluster.internal.
; replace `director` with the hostname of your DNS host, this should be the prefix of
the internal fqdn of the primary name server
; replace `10.5.0.4` with the internal IP of the primary name server
director
           A 10.5.0.4
```

## /etc/named/zones/db.reverse

```
$ORIGIN .
$TTL 600 ; 10 minutes
; replace `0.5.10.in-addr.arpa` with the the network component of your subnet, reversed
(the zone name defined in /etc/named/named.conf.local)
; replace `director.cdh-cluster.internal` with the internal fqdn of the primary name
server; note the trailing period (.)
; replace `hostmaster.cdh-cluster.internal` with the hostmaster email address, represented
with only periods (.), by convention this is `hostmaster.<your fqdn suffix>`; note the
trailing period (.)
0.5.10.in-addr.arpa IN SOA director.cdh-cluster.internal.
hostmaster.cdh-cluster.internal. (
        10
              ; serial
        600
              ; refresh (10 minutes)
        60
              ; retry (1 minute)
        604800 ; expire (1 week)
              ; minimum (10 minutes)
        600
      ; replace `director.cdh-cluster.internal` with the internal fqdn of your primary
name server; note the trailing period (.)
      NS director.cdh-cluster.internal.
; replace `0.5.10.in-addr.arpa` with the the network component of your subnet, reversed
 (the zone name defined in /etc/named/named.conf.local)
```

```
$ORIGIN 0.5.10.in-addr.arpa.
; replace `4` with the host number of the private IP of your DNS host; replace `director.cdh-cluster.internal` with the internal fqdn of your primary name
server
          PTR director.cdh-cluster.internal.
```

### Checking BIND Configuration

The syntax of BIND configuration files must be exact. Before starting the nameserver, check that the BIND configuration is valid.

```
# named-checkconf /etc/named.conf
```

Correct any errors. (Blank output means no errors exist.)

## Starting BIND

1. chown /etc/named\* to named:named (named requires read/write privileges):

```
# chown -R named:named /etc/named*
```

2. Start BIND:

```
# service named start
```

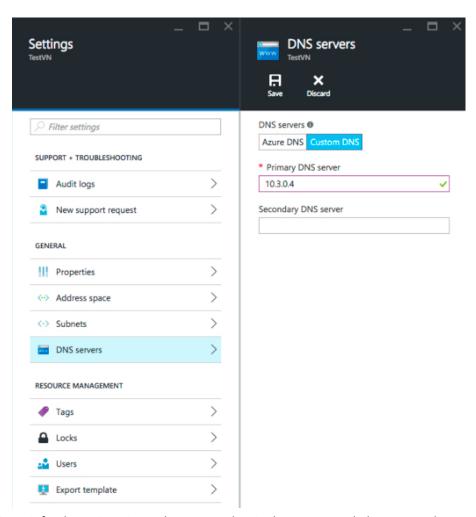

**3.** Set BIND to start on startup:

```
# chkconfig named on
```

### Swapping DNS from Azure to BIND

To change the DNS settings on Azure:

- 1. In the left pane, click Resource groups.
- **2.** Select the resource group your DNS server is in.
- **3.** Click on the virtual network your cluster is using.
- 4. Click settings.
- 5. Click DNS servers.
- 6. Set DNS servers to Custom DNS.
- 7. Set Primary DNS server to the private IP address of your Cloudera Director host (10.3.0.4 in this example).

- 8. Wait for the DNS setting update to complete in the Azure portal, then restart the network service on the VM. VMs created after the DNS setting is updated in the Azure portal automatically pick up the new DNS server address.
- 9. Restart the network service to pull down the nameserver changes entered in the Azure portal:

```
service network restart
```

If the change has propagated, the nameserver entry in /etc/resolv.conf reflects what you entered in the Azure portal:

```
cat /etc/resolv.conf
```

If the change has not yet propagated, wait two minutes and restart the network service again. You may have to do this multiple times.

#### RHEL 6 and CentOS 6: Add dhclient-exit-hooks

This script creates a new dhclient-exit-hooks file in /etc/dhcp/ and sets the file to be executable. Run the script as root:

```
#!/bin/bash
# cat a here-doc representation of the hooks to the appropriate file
cat > /etc/dhcp/dhclient-exit-hooks <<"EOF"</pre>
#!/bin/bash
printf "\ndhclient-exit-hooks running...\n\treason:%s\n\tinterface:%s\n" "${reason:?}"
 "${interface:?}"
```

```
# only execute on the primary nic
if [ "$interface" != "eth0" ]
then
    exit 0;
then
    printf "\tnew_ip_address:%s\n" "${new_ip_address:?}"
    host=$(hostname -s)
domain=$(nslookup $(grep -i nameserver /etc/resolv.conf | cut -d ' ' -f 2) | grep -i name | cut -d ' ' -f 3 | cut -d '.' -f 2- | rev | cut -c 2- | rev)

IFS='.' read -ra ipparts <<< "$new_ip_address"
    ptrrec="$(printf %s "$new_ip_address." | tac -s.)in-addr.arpa"
    nsupdatecmds=$(mktemp -t nsupdate.XXXXXXXXXX)
    resolvconfupdate=$(mktemp -t resolvconfupdate.XXXXXXXXXX)
    echo updating resolv.conf
    grep -iv "search" /etc/resolv.conf > "$resolvconfupdate"
    echo "search $domain" >> "$resolvconfupdate"
    cat "$resolvconfupdate" > /etc/resolv.conf
    echo "Attempting to register $host.$domain and $ptrrec"
        echo "update delete $host.$domain a"
        echo "update add $host.$domain 600 a $new_ip_address"
        echo "send"
        echo "update delete $ptrrec ptr"
        echo "update add $ptrrec 600 ptr $host.$domain"
        echo "send"
    } > "$nsupdatecmds"
    nsupdate "$nsupdatecmds"
fi
#done
exit 0;
```

### RHEL 7 and CentOS 7: Add NetworkManager Dispatcher Scripts

This script creates an /etc/NetworkManager/dispatcher.d/12-register-dns file and sets the file to be executable. Run the script as root:

```
#!/bin/bash
# CentOS and RHEL 7 use NetworkManager. Add a script to be automatically invoked when
interface comes up.
cat > /etc/NetworkManager/dispatcher.d/12-register-dns <<"EOF"</pre>
#!/bin/bash
# NetworkManager Dispatch script
# Deployed by Cloudera Director Bootstrap
# Expected arguments:
#
    $1 - interface
#
    $2 - action
#
# See for info: http://linux.die.net/man/8/networkmanager
# Register A and PTR records when interface comes up
# only execute on the primary nic
if [ "$1" != "eth0" ] || [ "$2" != "up" ]
then
   exit 0;
fi
# when we have a new IP, perform nsupdate
new_ip_address="$DHCP4_IP_ADDRESS"
host=$(hostname -s)
IFS='.' read -ra ipparts <<< "$new_ip_address"</pre>
```

```
ptrrec="$(printf %s "$new_ip_address." | tac -s.)in-addr.arpa"
nsupdatecmds=$(mktemp -t nsupdate.XXXXXXXXX)
resolvconfupdate=$(mktemp -t resolvconfupdate.XXXXXXXXXX)
echo updating resolv.conf
grep -iv "search" /etc/resolv.conf > "$resolvconfupdate"
echo "search $domain" >> "$resolvconfupdate"
cat "$resolvconfupdate" > /etc/resolv.conf
echo "Attempting to register $host.$domain and $ptrrec"
    echo "update delete $host.$domain a"
    echo "update add $host.$domain 600 a $new_ip_address"
    echo "send"
    echo "update delete $ptrrec ptr"
    echo "update add $ptrrec 600 ptr $host.$domain"
    echo "send"
} > "$nsupdatecmds"
nsupdate "$nsupdatecmds"
exit 0;
EOF
chmod 755 /etc/NetworkManager/dispatcher.d/12-register-dns
service network restart
```

#### Checking DNS

Azure has hooks to automatically overwrite /etc/resolv.conf with Azure-specific values. However, depending on OS, the contents of /etc/dhcp/dhclient-exit-hooks or

/etc/NetworkManager/dispatcher.d/12-register-dns are executed after the Azure hooks, and so can overwrite /etc/resolv.conf with custom values.

If you concatenate /etc/resolv.conf, it appears as follows:

```
; generated by /sbin/dhclient-script
nameserver 10.3.0.4
search cdh-cluster.internal
```

You can now resolve internal FQDNs and perform forward and reverse DNS queries without errors:

```
# hostname -f
director.cdh-cluster.internal
# hostname -i
10.3.0.4
# host `hostname -i`
4.0.3.10.in-addr.arpa domain name pointer director.cdh-cluster.internal
# host `hostname -f`
director.cdh-cluster.internal has address 10.3.0.4
```

Note that the values 10.3.0.4, 4.0.3.10, and cdh-cluster.internal are specific to this example and will be different for your implementation.

Errors like the following indicate that there is a problem with the DNS configuration:

```
# hostname -f
hostname: Unknown host
# hostname -i
hostname: Unknown host
# host `hostname -i`
Host 4.0.3.10.in-addr.arpa. not found: 3(NXDOMAIN)
```

## Setting Up MySQL or PostgreSQL

A database server can be installed on the same host as Cloudera Director and DNS, or you can add your database server to a different host in the same virtual network as Cloudera Director and the cluster. The supported databases are MySQL and PostgreSQL.

A dedicated database server is required for production clusters. The following steps are optional for non-production, proof-of-concept clusters.

#### **Database Server Requirements**

You can install a database server on the same host as the Cloudera Director server, a different host in the same Virtual Network as Cloudera Director and the cluster, or configure an existing database. Whichever method you choose, these are requirements for the database server:

- It must be JDBC accessible both locally and remotely.
- · The credentials provided to Cloudera Director must have superuser/administrator privileges.
- Increase the connection count according to Cloudera documentation on MySQL Database or PostgreSQL Database.
- Ensure sufficient CPU, memory, IOs, and bandwidth for the database server, especially if the database server is shared between multiple clusters.

## **Example for MySQL Installation**

For MySQL, follow the instructions in <u>Using MySQL for Cloudera Director Server</u>. Use the instructions for your specific version of MySQL, and keep in mind these additional requirements:

- Your MySQL server must be in the same virtual network as the rest of the cluster.
- Reference your MySQL server host by private IP address or an internal fully-qualified domain name (FQDN) that resolves to a private IP address.
- To reference the MySQL server by internal FQDN, make sure the MySQL server internal FQDN is registered with the DNS server you configured in Setting Up Dynamic DNS on Azure.

## Setting Up a Virtual Machine for Cloudera Director Server

Cloudera Director server is used to provision CDH clusters. See Create a Linux VM on Azure using the Portal in the Azure documentation for an overview of creating a Linux VM on Azure. We recommend using the CentOS image published by Cloudera on Microsoft Azure Marketplace.

Consider the following when creating a Linux VM:

- Instance size should be D3 or larger.
- Typically, install Cloudera Director in the same virtual network and subnet of the cluster.
- Typically, specify the same network security group.
- Typically, set the same availability as you set on the master nodes.
- A public IP address is optional, depending on the access pattern you use.

### Installing Cloudera Director Server and Client on Azure

To install Cloudera Director, follow the procedure for the OS you use. You must be running as root or using sudo to perform these tasks.

#### RHEL 7 and CentOS 7

- 1. SSH to the Azure instance you created for Cloudera Director.
- 2. Install a supported version of the Oracle Java Development Kit (JDK) on the Cloudera Director host. Cloudera Director supports JDK versions 7 and 8.

Note: Spark 2.2 requires JDK 8 and Python 2.7 or higher. For information on using Java 8 with Cloudera Director, see **Deploying a Java 8 Cluster**.

For download and installation information, see Java SE Downloads.

sudo yum localinstall jdk-version-linux-x64.rpm

**3.** Add the Cloudera Director repository to the package manager:

```
cd /etc/yum.repos.d/
sudo wget
"https://archive.cloudera.com/director/redhat/7/x86_64/director/cloudera-director.repo"
```

4. Install Cloudera Director server and client by running the following command:

```
sudo yum install cloudera-director-server cloudera-director-client
```

**5.** Start the Cloudera Director server by running the following command:

```
sudo service cloudera-director-server start
```

**6.** Disable and stop the firewall with the following commands:

```
sudo systemctl disable firewalld
sudo systemctl stop firewalld
```

#### RHEL 6 and CentOS 6

- 1. SSH to the Azure instance you created for Cloudera Director.
- 2. Install a supported version of the Oracle Java Development Kit (JDK) on the Cloudera Director host. Cloudera Director supports JDK versions 7 and 8. For download and installation information, see Java SE Downloads.

```
sudo yum localinstall jdk-version-linux-x64.rpm
```

**3.** Add the Cloudera Director repository to the package manager:

```
cd /etc/yum.repos.d/
sudo waet
"https://archive.cloudera.com/director/redhat/6/x86_64/director/cloudera-director.repo"
```

**4.** Install Cloudera Director server and client by running the following command:

```
sudo yum install cloudera-director-server cloudera-director-client
```

**5.** Start the Cloudera Director server by running the following command:

```
sudo service cloudera-director-server start
```

**6.** Save the existing iptables rule set and disable the firewall:

```
sudo service iptables save
sudo chkconfig iptables off
sudo service iptables stop
```

### Sample Configurations

Sample configuration files are available on the Cloudera GitHub site. You can modify these configuration files to create clusters using the Cloudera Director CLI.

- <u>azure.simple.conf</u>: A simple Cloudera Director configuration that creates a Cloudera Manager node and a four-node cluster (one master and three workers).
- <u>azure.reference.conf</u>: A reference Cloudera Director configuration that creates an eight-node cluster (three masters and five workers) with high availability (HA) enabled.
- <u>azure.kerberos.conf</u>: The same Cloudera Director configuration as <u>azure.reference.conf</u>, but with Kerberos enabled.

## Configuring a SOCKS Proxy for Microsoft Azure

For security purposes, Cloudera recommends that you connect to your cluster using a SOCKS proxy. A SOCKS proxy changes your browser to perform lookups directly from your Microsoft Azure network and allows you to connect to services using private IP addresses and internal fully qualified domain names (FQDNs).

This approach does the following:

- · Sets up a single SSH tunnel to one of the hosts on the network (the Cloudera Director host in this example), and create a SOCKS proxy on that host.
- Changes the browser configuration to do all lookups through that SOCKS proxy host.

## **Network Prerequisites**

The following are prerequisites for connecting to your cluster using a SOCKS proxy:

- The host that you proxy to must be reachable from the public Internet or the network that you are connecting from.
- The host that you proxy to must be able to reach the Cloudera Director server using a private IP. You can also proxy directly to the Cloudera Director server.

#### Start the SOCKS Proxy

To start a SOCKS proxy over SSH, run the following command:

```
ssh -i your-key-file.pem -CND 1080
the_username_you_specified@instance_running_director_server
```

#### The parameters are as follows:

- -i your-key-file.pem specifies the path to the private key needed to SSH to the Cloudera Director server.
- C sets up compression.
- N suppresses any command execution once established.
- D sets up the SOCKS proxy on a port.
- 1080 is the port to set the SOCKS proxy locally.

## Configure Your Browser to Use the Proxy Google Chrome

By default, Google Chrome uses system-wide proxy settings on a per-profile basis. To start Chrome without these settings, use the command line and specify the following:

- The SOCKS proxy port; this must be the same port you used when starting the proxy.
- The profile; this example creates a new profile.

This create a new profile and launches a new instance of Chrome that does not conflict with any currently running Chrome instance.

#### Linux

```
/usr/bin/google-chrome \
--user-data-dir="$HOME/chrome-with-proxy" \
--proxy-server="socks5://localhost:1080"
```

## Mac OS X

```
"/Applications/Google Chrome.app/Contents/MacOS/Google Chrome" \
--user-data-dir="$HOME/chrome-with-proxy"
--proxy-server="socks5://localhost:1080"
```

#### **Microsoft Windows**

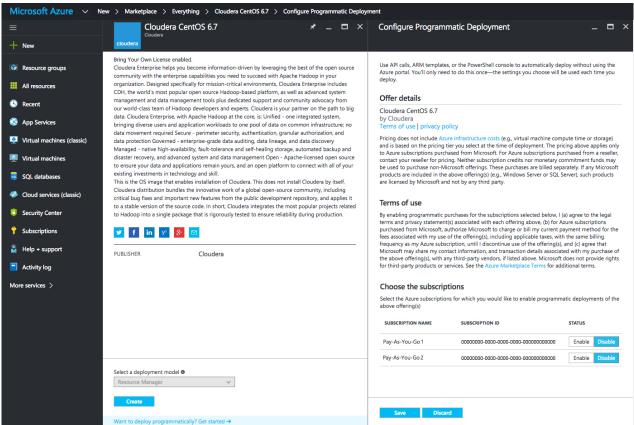

```
"C:\Program Files (x86)\Google\Chrome\Application\chrome.exe" ^
--user-data-dir="%USERPROFILE%\chrome-with-proxy"
--proxy-server="socks5://localhost:1080"
```

In this Chrome session, you can connect to any Cloudera Director-accessible host using the private IP address or internal FQDN. For example, if you proxy to the Cloudera Director server, you can connect to Cloudera Director as if it were local by entering localhost: 7189 in the Chrome URL bar.

## Allowing Access to VM Images

The Cloudera Director Azure plug-in deploys Azure VM images programmatically. To allow programmatic deployment of VM images on Azure, you must accept a term of usage and grant your Azure subscription permission to deploy the VM images.

By default, the Cloudera Director Azure plugin uses the Cloudera-certified CentOS 6 image. For detailed steps allowing programmatic deployment of Azure VM images, see a Working with Marketplace Images on Azure Resource Manager.

## Creating a Cluster

Before You Deploy Cloudera Manager and CDH

Important: Before using Cloudera Director to deploy clusters, make sure at least one VM has been manually deployed from the Azure portal into the Azure subscription you intend to use for your cluster.

This topic describes how to set up Cloudera Manager and a CDH cluster in Microsoft Azure using the Cloudera Director web UI. The following resources must be created and prerequisites must be met before beginning the deployment:

 An AD application and a service principal for the AD application. The AD application must have the contributor or similar role so that it has permission to create and delete resources in the subscription.

- A virtual network and network security group that is readily available for the cluster to use.
- The virtual network configured to use a customer-provided DNS service that supports reverse lookup. If using the provided DNS service setup guide, the VM that provides the DNS service must be created and running.
- Resource group to house cluster VMs.
- An Availability Set created in corresponding resource groups to house cluster VMs.
- Cloudera Director server VM.
- · Cloudera Director server installed and running.
- Cloudera Director server access to the Azure virtual network (VNet).
- Database server that is readily available and reachable from the VNet to be used by cluster nodes.

Details of setting up individual items above is covered in earlier sections.

## Deploying Cloudera Manager and CDH on Microsoft Azure

To deploy Cloudera Manager and CDH on an Azure VM instance, begin by creating an environment. The environment defines common settings, like region and key pair, that Cloudera Director uses with Azure. While creating an environment, you are also prompted to deploy its first cluster.

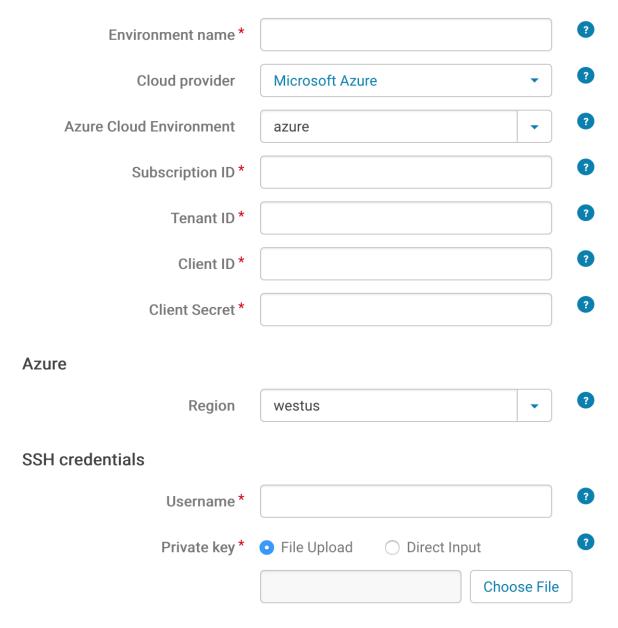

#### To create an environment:

- 1. Open a web browser and go to the private IP address of the instance you created running Cloudera Director server. Include port 7189 in the address, for example: http://192.0.2.0:7189.
- 2. In the Cloudera Director login screen, enter admin in both the Username and the Password fields.
- 3. In the Cloudera Director Welcome screen, click Let's get started. This opens a wizard for adding an environment, Cloudera Manager, and a CDH cluster.
- 4. In the Add Environment screen:
  - a. Enter a name in the Environment Name field.
  - **b.** In the Cloud provider field, select Azure Cloud Platform.
  - c. In the Azure Cloud Environment field, select which Azure Cloud to use.
  - d. In the Subscription ID field, enter the Azure subscription ID.
  - e. In the AAD URL field, enter the Azure Active Directory (AAD) URL provided by Microsoft. You do not need to change the default value unless you are in an Azure region that uses a different URL.
  - f. In the Tenant ID field, enter the ID of your ADD tenant. See Obtain Obtaining Credentials for Cloudera Director for details on obtaining the AAD tenant ID.
  - g. In the Client ID field, enter the client ID of the Azure service principal you created earlier. See Obtaining <u>Credentials for Cloudera Director</u> for details on obtaining the client ID.
  - h. In the Client Secret field, enter the client secret of the Azure service principal you created earlier. See Obtaining <u>Credentials for Cloudera Director</u> for details on obtaining the client secret.
  - i. In the **Region** field, select which location to use.
  - i. In the SSH Credentials section:
    - a. Enter a username in the Username field. Azure creates the user specified here.
    - **b.** Create an SSH key with the following command:

```
ssh-keygen -f ~/.ssh/my_azure_vm_keyname -t rsa
```

c. Copy the SSH private key into the **Private key** field. Cloudera Director uses the SSH key pairs to create and access VMs in Azure.

## **General Information**

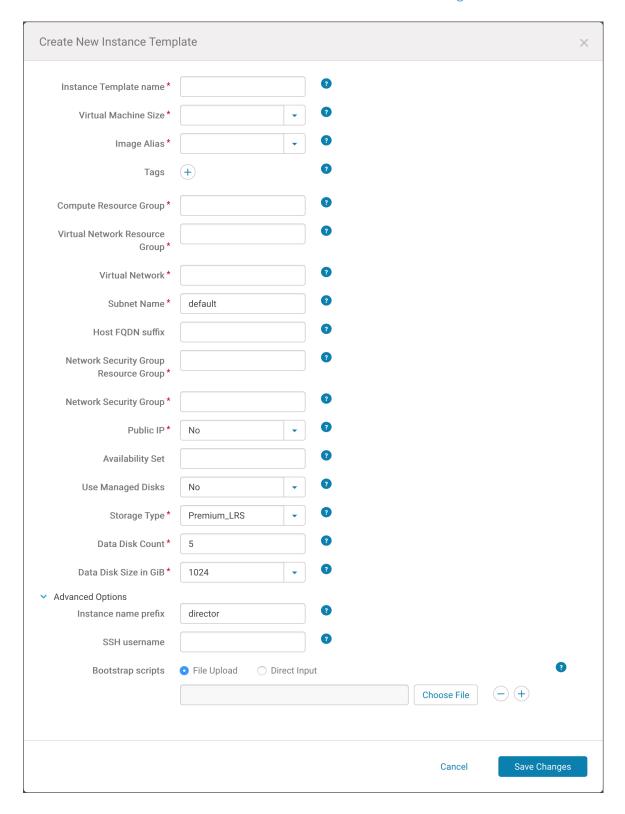

- **5.** Click **Continue** to add Cloudera Manager.
- **6.** In the **Add Cloudera Manager** screen:
  - a. Enter a name for this deployment of Cloudera Manager in the Cloudera Manager name field.
  - b. In the Instance Template field, select Create New Instance Template.
  - c. The Instance Template model screen displays.
- 7. In the Instance Template model screen:
  - **a.** In the **Instance Template** name field, enter a name for the template.
  - **b.** In the **VirtualMachine Size** field, select one of the available sizes.
  - c. In the Image field, select one of the available images or use this format to define any Azure Marketplace VM image inline (replace the italicized values with the actual names for the publisher, offer, sku, and version):

/publisher/publisher/offer/offer/sku/sku/version/version

- **d.** In the **Tags** field, add one or more tags to associate with the instance.
- e. In the Compute Resource Group field, enter the name of the resource group you created earlier to house the VM.
- f. In the Virtual Network Resource Group field, enter the name where the virtual network resource resides.
- **g.** In the **Virtual Network** field, enter the name of the virtual network.
- **h.** In the **Subnet Name** field, enter the name of the subnet you want to use.
- i. In the Host FQDN suffix field, enter the name of the host FQDN suffix you want your cluster host to use. This is the DNS domain of your cluster hosts.
- j. In the Network Security Group Resource Group field, enter the name of the resource group where the network security group resource resides.
- k. In the Network Security Group field, enter the name of the network security group.
- I. Select Yes in the Public IP field if you want to assign a public IP address to the VM. The default value is No.
- m In the Availability Set field, enter the name of the availability set you created in earlier steps. Note that there are two types of Availability Sets: managed (aligned) and unmanaged (classic). For more information see How to Use Availability Sets in the Microsoft Azure documentation.
- n. In the Use Managed Disks field, select Yes to use Managed Disks, or No to use Storage Accounts. Note the following considerations:
  - Azure Managed Disks are an improvement over Azure Storage Accounts. They simplify storage, provide better reliability for availability sets, and improve scalability. See Azure Managed Disks Overview in the Microsoft Azure documentation for more information.
  - A VM with Managed Disks can only be deployed into a managed Availability Set. For more information see <u>How to Use Availability Sets</u> in the Microsoft Azure documentation.
- o. In the Instance name prefix field under Advanced Options, enter the desired instance name prefix.
- p. In the Storage Account Type field, select Premium LRS. For instance templates intended for worker nodes, you can select Standard\_LRS. See the Cloudera Reference Architecture for Microsoft Azure Deployments for details on supported storage account types and configurations.
- q. In the Data Disk Count field in Advanced Options, enter the number of data disks to attach for the VM.
- r. In the Data Disk Size in GiB field, leave the value at 1024 or pick from the dropdown of available sizes.
- s. Leave the SSH username field blank to use the username you set at step 4.j above.
- t. In the Bootstrap script field in Advanced Options, paste or upload the desired custom bootstrap script.

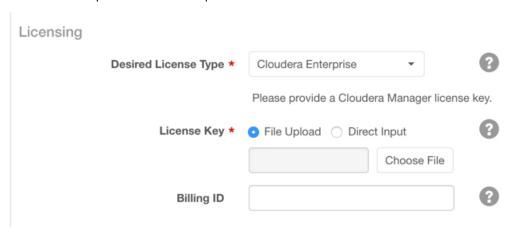

**Important:** If you created a DNS service following the DNS service setup guide, use this bootstrap script to ensure that the DNS record is updated correctly.

## **8.** In the **Desired License Type** field, select one of the following license types:

- Cloudera Enterprise: Includes the core CDH services (HDFS, Hive, Hue, MapReduce, Oozie, Sqoop 1, YARN, and ZooKeeper) and, depending on the license edition, one or more additional services (Accumulo, HBase, Impala, Navigator, Solr, or Spark). For more information on Cloudera Enterprise licenses, see Managing <u>Licenses</u> in the Cloudera Manager documentation.
- Cloudera Enterprise Trial: A 60-day trial license that includes all CDH services.

Cloudera Express: No license required.

To enable usage-based billing, you must have a Cloudera Enterprise license and a billing ID provided by Cloudera. In the Add Cloudera Manager screen:

- 1. In the Desired License Type field, select Cloudera Enterprise.
- 2. In the License Key field, either select a Cloudera Enterprise license file to upload or select Direct Input and input the license file text directly into the text area.
- 3. To enable usage-based billing, in the Billing ID field, enter the billing ID provided by Cloudera.
- 9. By default, the version of Cloudera Manager installed depends on the version of Cloudera Director you are using:

Cloudera Director version	Cloudera Manager version installed	
Cloudera Director 2.0	Latest released version of Cloudera Manager 5.5	
Cloudera Director 2.1	Latest released version of Cloudera Manager 5.7	
Cloudera Director 2.2	Latest released version of Cloudera Manager 5.8	
Cloudera Director 2.3	Latest released version of Cloudera Manager 5.10	
Cloudera Director 2.4	Latest released version of Cloudera Manager 5.11	
Cloudera Director 2.5	Latest released version of Cloudera Manager 5.12	
Cloudera Director 2.6	Latest released version of Cloudera Manager 5.13	

To install a version of Cloudera Manager higher or lower than the default version, perform the following steps:

- a. In the Configurations section, check Override default Cloudera Manager repository.
- b. In the Repository URL field, enter the repository URL for the version of Cloudera Manager to install. Repository URLs for versions of Cloudera Manager 5 have the form <a href="https://archive.cloudera.com/cm5/">https://archive.cloudera.com/cm5/</a> followed by the operating system, operating system major version, processor architecture, cm (for Cloudera Manager), and the Cloudera Manager major, minor, and (if applicable) maintenance release number. For example, for Cloudera Manager 5.5.4, the repository URL is <a href="https://archive.cloudera.com/cm5/redhat/7/x86\_64/cm/5.5.4/">https://archive.cloudera.com/cm5/redhat/7/x86\_64/cm/5.5.4/</a>.

Note: The Cloudera Manager minor version must the same as or higher than the CDH minor version. For example, Cloudera Manager 5.5 cannot be used to launch or manage a CDH 5.7 cluster, but Cloudera Manager 5.7 can be used with a CDH 5.7 or lower cluster.

- c. In the Repository Key URL field, enter the URL for the repository key. Repository key URLs have the same form as repository URLs except they end with the name of the key file instead of the Cloudera Manager version. For example, the repository key URL for any version of Cloudera Manager 5 on any supported version of Red Hat 7 is https://archive.cloudera.com/cm5/redhat/7/x86\_64/cm/RPM-GPG-KEY-cloudera.
- 10 In the Add Cloudera Manager screen, click Continue.

- **11** At the **Confirmation** prompt, click **OK** to begin adding a cluster.
- 12 On the Add Cluster screen:
  - a. Enter a name for the cluster in the Cluster name field.
  - b. Enter the version of CDH to deploy in the Version field, or leave the default value. By default, the version of CDH installed depends on the version of Cloudera Director you are using:

Cloudera Director version	CDH version installed	
Cloudera Director 2.0	Latest released version of CDH 5.5	
Cloudera Director 2.1	Latest released version of CDH 5.7	
Cloudera Director 2.2	Latest released version of CDH 5.9	
Cloudera Director 2.3	Latest released version of CDH 5.10	
Cloudera Director 2.4	Latest released version of CDH 5.11	
Cloudera Director 2.5	Latest released version of CDH 5.12	
Cloudera Director 2.6	Latest released version of CDH 5.13	

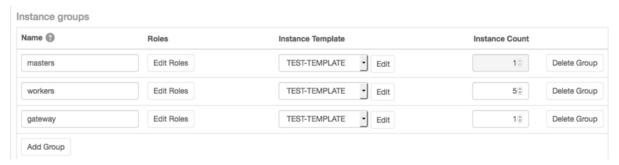

To install a version of CDH higher or lower than the default version, perform the following steps:

- a. Enter the desired CDH version in the Version field of the Products section. For example, for CDH 5.4.8, enter 5.4.8.
- **b.** Scroll down to **Configurations (optional)** and expand the section.
- c. Click Override default parcel repositories.
- d. Enter the repository parcel URL for the version of CDH you want to install. Parcel URLs for versions of CDH 5 have the form https://archive.cloudera.com/cdh5/parcels/, followed by the major, minor, and (if applicable) maintenance release number. For example, the URL for CDH 5.4.8 is https://archive.cloudera.com/cdh5/parcels/5.4.8.

Note: The CDH minor version must not be higher than the Cloudera Manager minor version. For example, CDH 5.7 does not work with Cloudera Manager 5.5, but CDH 5.7 or lower works with Cloudera Manager 5.7.

- **c.** In the **Services** section, select the services you want to install.
- d. In the Instance groups area, create a new template for the groups or for each group and the number of instances you want.

- 13 Click Continue.
- 14 At the confirmation prompt, click **OK** to deploy the cluster. Cloudera Director displays a status screen.

# **Status TESTCLUSTER01** Bootstrapping REQUESTING 7 INSTANCE(S) IN 3 GROUP(S) 1. Starting 2. Starting 3. Starting

15 When the cluster is ready, click Continue.

### Terminating Your Azure Deployment

When you are done testing or using Cloudera Director, terminate your instances to stop incurring charges to your Azure account.

- **1.** In Cloudera Director, terminate each instance in your clusters.
  - a. Click an environment name.
  - b. In the Actions column, select Terminate Cluster.
  - c. Repeat for each environment you configured.
- 2. To save anything in Cloudera Director (the configuration file or database, for example), back it up.
- 3. In the Azure web UI, terminate the Cloudera Director instance and any other instance Cloudera Director was unable to terminate.
- **4.** If applicable, terminate any external database you configured Cloudera Director to use.

## Adding New VM Images, Custom VM Images, Regions, and Instances

The Cloudera Director Azure Plugin supports adding new VM images, regions, and instances by modifying configuration files. For more information see Cloudera Director Azure Plugin Config Files on the Cloudera GitHub site.

See the Cloudera Reference Architecture for Microsoft Azure Deployments for the latest supported VM images, Azure regions, and instance types.

## Configuring and Deploying to Azure US Government and Azure Germany Regions

## Configuring and Deploying to Azure U.S. Government Regions

Azure U.S. Government is supported with no additional configuration needed. Just select azure-us-government in the Azure Cloud Environment field when adding a new environment.

### Configuring and Deploying to Azure Germany Regions

Azure Germany is supported with additional steps. Select azure-germany in the Azure Cloud Environment field when adding a new environment and follow the steps below.

Azure Germany API endpoints use a newer CA root certificate authority called D-TRUST. For more information, see the JDK release note New DTrust certificates added to root CAs and the section Certificate Changes: New DTrust certificates added to root CAs in the Oracle Java 7 Release Notes. This newer CA root certificate authority is not currently trusted by the default JDK that is installed via the Cloudera repository, jdk1.7.0\_67-cloudera.

In order for the plugin to work with Azure Germany, the JDK cacerts file must be replaced with a link to a newer version that includes the appropriate certificate with the following steps:

1. Confirm that /etc/pki/java/cacerts exists and contains the appropriate cert using keytool (keytool -list -v -keystore /etc/pki/java/cacerts). The necessary key is the one with CN=D-TRUST Root Class 3 CA 2 2009 SHA256: y

```
sudo my
/usr/java/jdk1.7.0_67-cloudera/jre/lib/security/cacerts
/usr/java/jdk1.7.0_67-cloudera/jre/lib/security/cacerts.original
```

```
sudo ln -s /etc/pki/java/cacerts
/usr/java/jdk1.7.0_67-cloudera/jre/lib/security/cacerts
```

**4.** You may have to restart Director to get it to pickup the new trusted cert database.

Note: You may have to undo the change in order for future updates to the JDK package to install properly.

#### **Deploying Clusters with Custom Images**

Note: Cloudera recommends that you use one of the Cloudera CentOS Virtual Machine images as the base for your custom images.

Deploying custom images is supported by updating instance template fields:

1. Set the Image field to be the Resource Id for the custom image. The Resource Id is on the Custom Image's Overview pane and is in the format (replace italicized words with your actual values):

/subscriptions/subscription-id/resourceGroups/resource-group-name/providers/Microsoft.Compute/images/custan-image-name

- 2. Set the Use Custom Managed VM Image field to Yes.
- 3. Set the Custom VM Image purchase plan field in this format (replace italicized words with your actual values):

/publisher/value/product/value/name/value

If there's no plan leave the field blank.

### Important Notes About Cloudera Director and Azure

#### Azure Limits, Quotas, and Constraints

Azure limits the number of CPU cores that can be allocated in each region. For details, see Azure subscription and service limits, quotas, and constraints in the Azure documentation. If you need to increase the limit, contact Microsoft Azure support before deploying the cluster with Cloudera Director.

Not all Azure VM types are available in all Azure regions. See Products available by region on the Microsoft Azure web site to confirm that a VM type is available in a particular region. See Cloudera Reference Architecture for Microsoft Azure Deployments for the latest supported VM types.

#### Azure Resources Managed by Cloudera Director

The Azure plug-in for Cloudera Director creates the following resources:

- Managed disks and storage accounts:
  - For VMs using unmanaged disks in storage accounts: one storage account for each VM.
  - For VMs using managed disks: one managed disk for each data disk, and one managed disk for the OS disk.
- A NIC for each VM.
- A public IP address for each VM, if public IP addresses are enabled.

#### **Deploying Production Clusters**

Although the Cloudera Director web UI can be used for proof-of-concept deployments on Azure, you must use the published sample configuration files for production deployments (see <u>Useful Links</u> below). You can modify the sample

configuration file to fit your specific deployment environment, remove services you do not need, and customize the sample bootstrap script. Configurations related to logging and data storage for individual services must not be changed. Deploying a cluster using the Cloudera Director command-line interface and configuration file based on the examples ensures a repeatable deployment with the proper settings for Azure.

See the Cloudera Reference Architecture for Microsoft Azure Deployments document for more details.

## Updating the Azure Plug-in Timeout Value

Azure backend operations usually complete in a few minutes, but in rare cases they take longer, sometimes up to an hour. This can cause Cloudera Director operations such as allocate to fail prematurely. If this happens, you may want to increase the backend polling timeout value in the azure-plugin.conf file.

- 1. Download the latest supported azure-plugin.conf file from the Cloudera Director scripts repository.
- $\textbf{2. Find the parameter} \ \texttt{azure-backend-operation-polling-timeout-second} \ \textbf{in the provider section}.$
- **3.** Change the value to the required duration in seconds.
- 4. On the Cloudera Director server, copy the modified azure-plugin.conf to /var/lib/cloudera-director-plugins/azure-provider-x.x.x/etc/azure-plugin.conf (replacing x.x.x with the latest version), and then restart Cloudera Director with sudo service cloudera-director-server restart

This procedure changes only the Azure plug-in timeout. The following Cloudera Director timeout values must also be increased in the server's application.properties file to be at least as large as the Azure plug-in configuration values:

- lp.cloud.databaseServers.allocate.timeoutInMinutes
- lp.cloud.instances.terminate.timeoutInMinutes

See Setting Cloudera Director Properties for information on setting configuration properties in the server's application.properties file.

#### **Deletion Behavior**

The deletion behavior is as follows:

- The storage used for the VM OS disk and cluster data disks.
- The NIC created by the plug-in is attached to the VM. Only one NIC is used per VM. Do not manually attach NICs to the VM created by the plug-in.
- If the VM was set up to have a public IP, Cloudera Director will delete it. If a public IP was attached manually after the VM was created, Cloudera Director will not delete it.

Important: Based on the deletion behaviors described, do not reuse any resources created by the Azure plug-in for any other purpose.

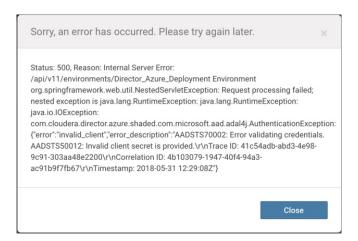

## **Updating an Expired Azure Client Secret**

The Azure client secret is a necessary part of Microsoft Azure security. Cloudera Director uses the combination of your Azure Active Directory application tenant ID, client ID, and client secret to authenticate, and thereby perform actions against Azure.

Note: For more information, see <u>Use portal to create an Azure Active Directory application and service</u> principal that can access resources.

If your client secret expires, you will get an error in the Cloudera Director UI similar to the following:

An expired client secret also results in an entry similar to the following in the Cloudera Director log file:

```
Failed to authenticate with Azure: java.io.IOException:
com.cloudera.director.azure.shaded.com.microsoft.aad.ada14j.AuthenticationException:
{"error":"invalid_client","error_description":"AADSTS70002: Error validating
credentials. AADSTS50012: Invalid client secret is provided.\r\nTrace ID:
fc5529da-2536-44f6-bad4-d07f6a9bbd00\r\nCorrelation ID:
1e7f12f3-32e7-4635-8b27-197e53fd0ab8 \verb|\r| nTimestamp: 2018-05-31
11:13:11z"}
```

#### Steps to Update an Expired Client Secret

To update an expired client secret, perform the following steps for each environment that uses the expired secret.

Note: This procedure works for Cloudera Director 2.6 and higher. If you are using a lower version of Cloudera Director, contact Cloudera Support for assistance.

- 1. Turn off credential validation.
  - a. ssh to the Cloudera Director server host.
  - **b.** Locate the Azure plugin configuration file if you have one, or create a new plugin configuration file.

Note: Whether an Azure plugin configuration file exists on your system will depend on how Cloudera Director was initially installed and whether any plugin configuration settings have already been changed.

- **a.** If you already have a configuration file, it will be located at
- **b.** If there is no azure-plugin.conf file at that location, create one by running the following command:

/var/lib/cloudera-director-plugins/azure-provider-version/etc/azure-plugin.conf.

wget -0 /var/lib/cloudera-director-plugins/azure-provider-version/etc/azure-plugin.conf  $\verb|https://raw.githubusercontent.com/cloudera/director-scripts/master/azure-plugin-config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.config/azure-plugin.co$ 

c. Edit the azure-plugin.conf file. Towards the end of the file there's an azure-validate-credentials field. Change the value to false:

```
azure-validate-credentials: false
```

2. Restart Cloudera Director:

```
sudo service cloudera-director-server restart
```

**3.** Update the credentials in either of the following ways:

- Using the Cloudera Director UI:
  - 1. Log into Cloudera Director and go to the environment whose client secret has expired.
  - 2. From the Add Cloudera Manager dropdown menu, select Update Environment Credentials.
  - **3.** Put in the new client secret along with your existing settings for this environment. Existing environment settings can be found under the **Details** tab.
- Using the Cloudera Director API:
  - 1. Log into Cloudera Director. (You must be authenticated to use the Cloudera Director API.)
  - **2.** Go the the **environments** section of the API console of your Cloudera Director server (replace director-server-hostname with your own):

```
http://director-server-hostname:7189/api-console/index.html#
```

- **3.** Click on the GET /api/v11/environments section, and click **Try it out!** to list the environments. If you are using a version of the API other than v11, this procedure will still work, but your URL will contain the version you are using in place of v11.
- **4.** Copy the name of the environment whose client secret has expired. Open the GET /api/v11/environments/{name} section and paste the environment name into the name parameter box, and click **Try it out!** to display the environment details.
- 5. Copy the config portion of the JSON block including the curly braces but excluding the "config" string. It should similar to the example below. You might have different fields and values, but clientSecret should be there. If the clientSecret field is not there, check to be sure you are using the correct API.

```
{
    "tenantId": "[...]",
    "region": "eastus2",
    "azureCloudEnvironment": "azure",
    "clientSecret": "REDACTED",
    "subscriptionId": "[...]",
    "clientId": "[...]"
}
```

- 6. Open the PUT /api/v11/environments/{name}/provider/credentials section. Note that there is /provider/credentials in the path it is NOT the PUT /api/v11/environments/{name} section.
- **7.** Paste in the whole JSON block, including all fields and the surrounding curly braces, and then edit the JSON block:
  - Remove the "region" line.
  - Replace the "REDACTED" portion of "clientSecret": "REDACTED" with your new client secret.
- **8.** Click **Try it out!** again to update the credentials. On success, you should get a 202 response code. If you get a 400 Bad Request, check the Cloudera Director logs for full details. Also, check that you have not made any of the following common mistakes:
  - a. Using PUT /api/v11/environments/{name} instead of PUT /api/v11/environments/{name}/provider/credentials (note the /provider/credentials in the path).

This causes the following response:

```
"status": 400,
"error": "Bad Request",
"exception":
"org.springframework.http.converter.HttpMessageNotReadableException",
"message": "Bad Request"
```

• b. Improperly formatted JSON. This causes the following response:

```
"status": 400,
   "error": "Bad Request",
  "exception":
org.springframework.http.converter.HttpMessageNotReadableException",
   "message": "Bad Request"
```

• c. Forgetting to remove the "region" line. This causes the following response:

```
"status": 400,
   "error": "Bad Request",
   "exception":
"com.cloudera.launchpad.api.common.EnvironmentsResource$UnsupportedEnvironmentUpdateException",
   "message": "Unsupported environment update request"
```

- **4.** Turn on credential validation. In this step, you undo what you did in the beginning:
  - If you did not have an azure-plugin.conf file initially, delete the file now.
  - If there was a file initially, then change azure-validate-credentials in your azure-plugin.conf back to true:

```
azure-validate-credentials: true
```

5. Restart Cloudera Director:

```
sudo service cloudera-director-server restart
```

- **6.** Verify the fix.
  - a. Tail the logs on the Cloudera Director host:

```
tail -f /var/log/cloudera-director-server/application.log
```

- b. Log into the Cloudera Director UI and go to the environment whose client secret was previously expired.
- c. If there are no errors with credential validation in the Cloudera Director UI or in the logs, then the new client secret has been applied.

If you see the following message in the logs after restarting Cloudera Director, credential validation is still turned off (azure-validate-credentials: false):

```
Skipping Azure credential validation with Azure backend.
```

Verify that everything was changed back correctly, and that Cloudera Director was restarted.

#### **Useful Links**

- Cloudera Enterprise Reference Architecture for Azure Deployments.
- Configuration files for running Cloudera Director on Microsoft Azure:
  - azure.simple.conf: A simple Cloudera Director configuration that creates a Cloudera Manager node and a four-node cluster (one master and three workers).
  - <u>azure.reference.conf</u>: A reference Cloudera Director configuration that creates an eight-node cluster (three masters and five workers) with high availability (HA) enabled.
  - <u>azure.kerberos.conf</u>: The same Cloudera Director configuration as <u>azure.reference.conf</u>, but with Kerberos enabled.

# **Usage-Based Billing**

Cloudera Director 2.1 and higher includes an automated metering service that enables usage-based billing, so that you only pay for the services you use. This section describes how usage-based billing works in Cloudera Director.

## **Prerequisites**

The following are required for usage-based billing:

- · Cloudera Director 2.1 or higher
- A billing ID provided by Cloudera. Your billing ID ensures that the Cloudera Manager instance and the clusters it manages are associated with your customer account, so that metering of your cluster usage is accurate.
- A Cloudera Enterprise license. When you provide a Cloudera Enterprise license and a billing ID during deployment
  of Cloudera Manager, usage-based billing is enabled for all clusters created with that Cloudera Manager instance.
  If you do not add a billing ID, usage-based billing is not enabled, and you are charged for your clusters under
  normal node-based billing.
- An account on a cloud service supported by Cloudera Director to deploy Cloudera Manager and CDH.
- Outbound HTTPS connectivity from Cloudera Director to Cloudera's metering service at
   <a href="https://metering.cloudera.com">https://metering.cloudera.com</a> and the endpoints within AWS where usage information is collected. If outbound internet connectivity is restricted by your organization's security policies, then HTTPS connectivity can be narrowed to the <a href="https://www.aws.new.organization">AWS IP address ranges</a>.
- At least 2 GB of free disk space should be available on the Cloudera Director server to store usage information until it can be transmitted to the metering service.

# How Usage-Based Billing Works

When usage-based billing is enabled, Cloudera Director collects cluster usage information at regular intervals in the form of usage bundles. The usage bundles are sent to a metering service that aggregates the information and determines the total bill.

The price for usage-based billing is determined by three factors:

- The Cloudera hourly rate, which is determined by two factors:
  - Instance type
  - CDH services enabled on the cluster
- Number of instances
- Number of hours

Hours billed are based on the time the instance or service starts, not on the time of day. Portions of an hour are rounded up to the next full hour. For example, an instance that runs from 1:40 pm. to 2:20 p.m. is charged for one hour.

Charging for instances in a cluster begins when bootstrapping is complete and the appropriate components have been installed and started on that cluster. The applicable rate is determined by the components that are deployed on the cluster for a given hour, so the price can change when a component is added or removed that would affect the rate.

There is no charge for instances in a cluster where none of the services are running, and billing stops for all instances in the cluster if the cluster is stopped or terminated. Billing and collection of usage information also stops if Cloudera Director is stopped. Billing resumes when Cloudera Director is started, but the billing hour for all billable clusters is reset from when Cloudera Director restarts.

The price charged for a running cluster depends partly on the CDH services it contains. The following table shows the five types of clusters defined for billing purposes, from least to most expensive.

Basic	Data Engineering	Operational DB	Analytic Database	Data Hub
"Core Hadoop"	"Core Hadoop" + Spark, Search	"Core Hadoop" + HBase, Spark, Search	"Core Hadoop" + Impala	All Capabilities

Usage-based billing only applies to your use of Cloudera Director, Cloudera Manager, and CDH services in the cloud. You are billed directly by your cloud provider for all cloud provider services, such as the virtual instances and databases used by your clusters.

Contact Cloudera for additional details about pricing with usage-based billing.

# Deploying Cloudera Manager and CDH with Usage-Based Billing

When you create an instance of Cloudera Manager with a Cloudera Enterprise license and a billing ID, usage-based billing is enabled for all clusters you launch through that Cloudera Manager instance.

You can deploy Cloudera Manager and create clusters with usage-based billing either through the Cloudera Director server web UI or with the Cloudera Director client and the bootstrap-remote command, as described in this section.

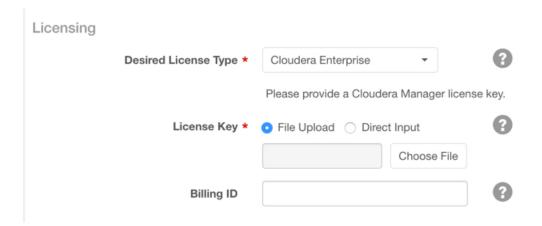

## Enabling Usage-Based Billing with the Cloudera Director Server web UI

The procedure for deploying Cloudera Manager and CDH through the Cloudera Director web UI is described in Deploying Cloudera Manager and CDH on AWS on page 57. To enable usage-based billing, follow the procedure as described there, but be sure to provide a Cloudera Enterprise license and a billing ID as described in the steps for the Add Cloudera Manager screen.

If you choose Cloudera Enterprise, the License Key and Billing ID fields are displayed. The Billing ID field is optional. Enter a valid license key, but do not enter a billing ID if you want your clusters to include Cloudera Enterprise features but without usage-based billing.

Note: If you deploy Cloudera Manager with a Cloudera Enterprise license but without a billing ID, you can add a billing ID later and launch clusters with usage-based billing. But you cannot add a Cloudera Enterprise license to an instance of Cloudera Manager that was created with a Cloudera Enterprise Trial or Cloudera Express license. If your Cloudera Manager instance does not have a Cloudera Enterprise license, you must deploy another Cloudera Manager instance with a Cloudera Enterprise license in order to use usage-based billing.

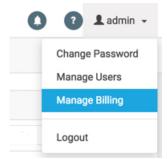

## Enabling Usage-Based Billing with bootstrap-remote

The procedure for deploying Cloudera Manager and CDH through the Cloudera Director client using the bootstrap-remote command is described in Submitting a Cluster Configuration File on page 202.

There is a <u>sample Cloudera Director CLI configuration file</u> for remote bootstrapping a cluster on AWS with usage-based billing enabled. This configuration file will create a basic cluster with a Cloudera Enterprise license and billing ID. Edit the file to provide your license and billing ID, your credentials for your cloud provider, and configurations for your desired cluster services.

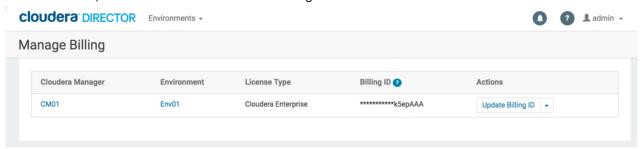

# Managing Billing IDs with an Existing Deployment

To manage billing IDs for an existing deployment of Cloudera Manager, click **Manage Billing** on the admin menu in the upper right of the Cloudera Director web UI.

The Manage Billing page displays information about Cloudera Manager instances and environments managed by Cloudera Director.

If a Cloudera Manager instance has a Cloudera Enterprise license and a billing ID, the billing ID is displayed on this page in redacted form, as shown here for the Cloudera Manager instance CM01:

If a Cloudera Manager deployment has a Cloudera Enterprise license but does not have a billing ID, as shown above for the deployment CM02, the value of the **Billing ID** for that instance is **Not Assigned** and usage-based billing is not enabled. You can add a billing ID for that Cloudera Manager deployment to enable usage-based billing. To add a billing ID to an existing Cloudera Manager deployment:

- 1. On the Manage Billing page, click Assign Billing ID to open the Update Billing ID dialog.
- 2. Enter a valid billing ID.
- 3. Click Update.

To replace a billing ID with a different one:

- 1. Click Update Billing ID.
- 2. In the **Update Billing ID** dialog, enter the new billing ID.
- 3. Click Update.

# Troubleshooting Network Connectivity for Usage-Based Billing

If Cloudera Director is unable to connect to or upload usage information to the metering service, or is unable to connect to Cloudera Manager to obtain the usage information, an alert appears under the bell icon at the upper right of the top banner in the Cloudera Director web UI, and the bell icon turns red. Click the icon to see the alert.

If Cloudera Director is unable to connect to or upload usage information to the metering service, the alert will say:

 Cloudera Director is unable to send usage data to Cloudera's billing service at https://metering.cloudera.com. Check that your network is configured to allow sending of usage data and that Cloudera's billing service is running.

If Cloudera Director is unable to connect to Cloudera Manager, the alert will say, for example (with actual values for the names of your Cloudera Manager instance and environment, and time elapsed):

• Unable to connect to cm1 in env2 for at least 2 minutes 18 seconds. Check your deployment status. The deployment may have failed or may have a connectivity issue.

When an alert appears, check the network and security configuration where Cloudera Director is running:

- Check that the firewall rules for your Cloudera Director instance (for example, the security group for an AWS EC2 instance) are configured to permit network access to the internet.
- Check that the subnet for the Cloudera Director instance has a route to the internet.
- · Check in the Cloudera Director web UI to ensure that Cloudera Director is able to connect to the Cloudera Manager instance.
- Open a shell on the Cloudera Director instance and try to ping a publicly-accessible URL, such as www.cloudera.com.
- Using a machine in your local network environment (outside of the network environment where Cloudera Director is running), send a ping request from a web browser to the collection service ping endpoint at this URL: https://metering.cloudera.com/api/v1/ping. If the metering service is not reachable, the service may be down. Contact Cloudera Support.

# Cloudera Director Usage Bundles

A Cloudera Director usage bundle is a JSON document representing a snapshot in time of Cloudera Manager and cluster usage. It contains three sections: a metadata section, a Cloudera Manager block, and a Cloudera Director block.

Note: All passwords and sensitive information included in Cloudera Director usage bundles are redacted.

## Metadata Section

The short metadata section in a usage bundle contains:

- The version of the metadata structure
- The complete license key and billing ID for the deployment
- The creation time of the bundle
- A message ID structure, used by Cloudera's metering service for context and sequencing

## Cloudera Manager Block

The Cloudera Manager block contains information queried from Cloudera Manager about itself and clusters that it

Initial metadata in the block includes the metadata structure version and the host, port, and API version of Cloudera Manager itself.

Next, the block contains details about Cloudera Manager itself, as retrieved from its /cm/deployment API endpoint. See the Cloudera Manager REST API documentation for complete information. The data is retrieved from Cloudera Manager using its **export redacted** view, which eliminates sensitive configuration information such as passwords. This deployment data includes information about all clusters and their services, all hosts, and all management services. Some specific data items in the details are:

- · Cluster, service, and role names
- · Service and role configurations (redacted) and health statuses
- Cloudera Manager's internal user accounts, with redacted passwords
- · Instances' Cloudera Manager host identifiers, private IP addresses, and private host names

Instances' core counts and memory sizes

Finally, the block includes time series data for the capacity and used capacity of each filesystem associated with the Cloudera Manager instance and with every instance that is part of a cluster. The data covers the five minutes prior to the bundle's creation. See the Cloudera Manager REST API documentation for complete information on the data structures in a time series. Instance private IP addresses and host names are included in the time series data.

#### Cloudera Director Block

The Cloudera Director block contains information queried from Cloudera Director itself about Cloudera Manager installations and clusters that it manages. For complete information on the data structures described here, consult the <u>Cloudera Director API documentation</u> or explore using the API console included with Cloudera Director, at the /api-console URL.

Initial metadata in the block includes the metadata structure version and the host, port, and API version of Cloudera Director itself. Ensuing details begin with the version of Cloudera Director and the time when the block was created.

Next, the block includes the deployment template used to create the Cloudera Manager installation. The data retrieved from Cloudera Director here is redacted, eliminating potentially sensitive information such as external database account details and inline scripts. Some specific data items are:

- Redacted license and billing ID (which are available unredacted in the usage bundle metadata)
- External Cloudera Manager database templates, if any
- The Cloudera Manager instance template

After some deployment health and status information, details about the running deployment are included. As with the deployment template information, deployment information is redacted to eliminate potentially sensitive information such as the Cloudera Manager administrator password. Some specific data items are:

- The Cloudera Manager version and private IP address
- Details about the instance running Cloudera Manager, including its public and private IP addresses and host names, information specific to the cloud provider such as virtual network and subnet identifiers, its installed software capabilities, and its instance template
- The Cloudera Manager port and administrative username

Next, the cluster templates for each of the clusters created by Cloudera Director are listed. As with other Cloudera Director API calls, cluster template information such as inline scripts is redacted for security. Some specific data items are:

- The cluster template name and list of services deployed
- External service database templates, if any
- · Virtual instance groups and associated instance templates

Finally, after some cluster status and health information, details about each bootstrapped cluster are provided. Sensitive information is left out of these query results like the rest. Some specific data items are:

- Overall cluster health and individual service health checks
- Installed software capabilities of each cluster instance

### Usage Logging

Cloudera Director is capable of logging usage bundles and heartbeats as they exist immediately before submission to Cloudera's metering service. The logging is disabled by default, but it can be enabled and configured to provide visibility into precisely what Cloudera Director is sending out.

To enable usage logging in the Cloudera Director server, locate the logback.xml file used to configure its logging system. The file is normally in /usr/lib/cloudera-director-server/etc [check this]. Look for the configurations for the following loggers:

- com.cloudera.director.metering.heartbeats
- com.cloudera.director.metering.bundles

Change the level for each logger to INFO to enable usage logging. To disable usage logging, change the level back to **ERROR**. After changing the level, restart Cloudera Director so that the change takes effect.

The logging configuration writes the JSON for heartbeats and usage bundles to a dedicated log file. Those comfortable with configuring the Logback logging system can make further changes to have the information written elsewhere. Consult Logback documentation for the options available.

Usage logging increases the demand for file storage on the Cloudera Director instance. Do not enable it for long periods of time, to avoid running out of disk space.

# **Using Cloud Provider Regions**

This section explains how to use cloud provider regions with Cloudera Director.

# Running Cloudera Director and Cloudera Manager in Different Regions or Clouds

A Cloudera Director instance requires network access to all of the Cloudera Manager and CDH instances it deploys and manages. If Cloudera Director is installed in the same subnet where you install Cloudera Manager and create CDH clusters, this requirement is satisfied automatically. However, the following alternative configurations are also supported:

- Running Cloudera Director in one region and Cloudera Manager and the CDH clusters it manages in a different
- Installing Cloudera Director on one cloud provider, such as AWS, and Cloudera Manager and the CDH clusters it manages on a different cloud provider, such as Microsoft Azure or Google Cloud Platform.
- Installing Cloudera Director in your local network environment (on your laptop, for instance), and Cloudera Manager and the CDH clusters it manages in a cloud environment.

The most secure solution in these cases is to set up a VPN giving Cloudera Director access to the private subnet. Alternatively, Cloudera Director can be given SSH access to the instances through the public internet.

When using SSH to configure Cloudera Manager and CDH instances, Cloudera Director will try to connect to the instances in the following order:

- Private IP address
- 2. Private DNS host name
- 3. Public IP address
- 4. Public DNS host name

The following requirements apply to running Cloudera Director and clusters in different regions or cloud provider environments when connecting to instances through their public endpoints:

- Your cluster instances must have public IP addresses and your security group must allow SSH access on port 22 from the IP address of the Cloudera Director host.
  - For AWS: If you are creating the cluster with the UI, set Associate public IP addresses to true in the Environment for Cloudera Manager and the cluster. If you are creating the cluster with the CLI, set the associatePublicIpAddresses to true in the configuration file.
  - For Microsoft Azure: If you are creating the cluster with the UI, set Public IP to Yes in the instance template for Cloudera Manager and the cluster. If you are creating the cluster with the CLI, set publicIP to Yes in the configuration file.
- While Cloudera Director can run in a different subnet, Cloudera Manager and the CDH cluster hosts must be in the same subnet.
- Cloudera Director must have SSH access to the public IP addresses of all cluster instances.
- Cloudera Director needs to communicate with Cloudera Manager on its API endpoint (typically through HTTP to port 7180) on the private IP address. For security reasons, this endpoint should not be exposed to the public internet.
  - For Cloudera Manager instances that were deployed by Cloudera Director, if Cloudera Director cannot make a direct connection to the Cloudera Manager API on the private IP address, it will automatically attempt to create an SSH tunnel to the Cloudera Manager API endpoint through an SSH connection to the instance on its public IP address.
  - Connecting to an existing deployment of Cloudera Manager through SSH tunneling is not supported.

# Using a New AWS Region in Cloudera Director

Cloudera Director's AWS support, embodied in a plugin, ships with a predefined, known set of AWS regions. Cloudera adds support for additional regions when possible in new Cloudera Director releases. But, because you may want to use a new region before it has been added in a new release, Cloudera Director makes it possible to add the new region yourself.

Note: Examples here use the region code xy-east-1 as an example of a new region. Use the code for the region you want to use instead.

For more information about AWS regions, see Regions and Availability Zones in the AWS documentation.

## **Entering the Region Code**

When using its web interface, Cloudera Director asks you which region to use when you define a new AWS environment. You can select the region for EC2, where instances hosting Cloudera Manager and cluster components run, and for RDS, where an external database server can house databases for Cloudera Manager and services like Hive and Oozie.

The region selection widgets are ordinary drop-down menus, but the menus are also editable. To use a region that isn't listed, just type in its region code.

When you use Cloudera Director's configuration file support for defining new deployments and clusters, you don't have any widgets. Simply supply the region code for EC2 and RDS in the expected locations.

- EC2 region: in the provider section, as the region field
- RDS region: in the provider section, as the rdsRegion field. If the region is not specified, it defaults to the EC2 region

## **Region Endpoints**

In most cases, Cloudera Director can figure out the AWS endpoints for the different services in a region, so just naming the new region is enough to get things moving. If you receive errors that an AWS service could not be reached, you may need to specify some endpoints, as described below for RDS, IAM, and KMS.

For general information about region endpoints in AWS, see AWS Regions and Endpoints in the AWS documentation.

### RDS

If you plan on using RDS, you must supply the RDS endpoint for your chosen region. There are two ways to do this.

 Using the web UI interface, specify the endpoint URL directly when you define your environment. In the web interface, expand the Advanced Options section under RDS (Relational Database Service) and enter the endpoint URL for RDS region endpoint. In a configuration file, give the URL as the value for the rdsRegionEndpoint field in the provider section. Here is what an endpoint URL looks like:

```
rdsRegionEndpoint: https://rds.xy-east-1.amazonaws.com
```

 Rather than specifying the RDS endpoint URL with each environment you create, you can supply it in a configuration file that is read by Cloudera Director's AWS plugin, so it will be used for all environments created with that instance of Cloudera Director. The configuration file is named rds.endpoints.properties and, by default, resides in the directory /var/lib/cloudera-director-plugins/aws-provider-version/etc/. The version number for the aws-provider part of the path changes with most Cloudera Director releases, as the plugin changes version. For example, aws-provider-1.4.1 matches with Cloudera Director 2.4. So the path and file name with Cloudera Director 2.4 would be as follows:

/var/lib/cloudera-director-plugins/aws-provider-1.4.1/etc/rds.endpoints.properties

#### **Using Cloud Provider Regions**

Cloudera Director ships with an example of the file that you can use as a template: rds.endpoints.properties.example. Copy this file to a new rds.endpoints.properties file in that directory, and add a line for the RDS endpoint URL, for example:

```
xy-east-1=https://rds.xy-east-1.amazonaws.com
```

After adding a new endpoint, restart Cloudera Director if it is running.

#### IAM

The IAM service is normally accessed using a single, global endpoint that works across all AWS regions. Some regions, however, have their own IAM endpoint. If you are using such a region, supply its custom IAM endpoint. When using the web interface, expand the Advanced Options section under EC2 (Elastic Compute Cloud) on the environment page, and enter the endpoint URL for IAM endpoint. In a configuration file, specify it in the field iamEndpoint in the provider section.

```
iamEndpoint: https://iam.xy-east-1.amazonaws.com
```

#### **KMS**

Cloudera Director normally computes the expected KMS endpoint for your chosen region. If that process fails, then you can provide the endpoint URL yourself. In the web interface, expand the Advanced Options section under EC2 (Elastic Compute Cloud) on the environment page, and enter the endpoint URL for KMS region endpoint. In a configuration file, specify it in the field kmsEndpoint in the provider section.

```
kmsEndpoint: https://kms.xy-east-1.amazonaws.com
```

#### Other Considerations

A new AWS region usually does not support the full range of services and features that are available in older, established regions. It's important to understand what services and features your chosen region lacks, so that you do not request them through Cloudera Director. Cloudera Director does not retain knowledge on which regions have which services available.

Here are some examples of items that can work in older regions but not fully, or at all, in newer ones.

- AMIs common "stock" AMIs may not exist for new regions
- instance types deprecated instance types are often left out of new regions
- dedicated instances (tenancy)
- Spot blocks
- RDS instance encryption

# Configuring Storage for Cloudera Director

This section explains options for configuring storage for Cloudera Director. A number of kinds of storage and storage options are available with Cloudera Director. You can use an external database for Cloudera Director server in place of the embedded H2 database, and doing so is highly recommended for production installations. Cloudera Director supports MySQL and MariaDB for this purpose. Also, you can configure Cloudera Director to encrypt the data stored in the Cloudera Director database. These options are described in the following sections.

# Using MySQL for Cloudera Director Server

Note: This section is about the data Cloudera Director server stores for its own use. You can also use external databases for Cloudera Manager and cluster services. For more information, see Using an External Database for Cloudera Manager and CDH on page 136.

Note: For information on configuring Cloudera Director and the MySQL database to communicate using TLS, see Enabling TLS with Cloudera Director, and especially the section, TLS for Cloudera Director's Database on page 162.

Cloudera Director stores various kinds of data, including information about deployments, database servers, users, CDH clusters, and Cloudera Manager instances. By default, this data is stored in an embedded H2 database stored on the filesystem where the server is running at the following location:

/var/lib/cloudera-director-server/state.h2.db

Alternatively, you can use a MySQL database instead of the embedded H2 database, as described below.

## Installing the MySQL Server

#### Note:

- If you already have a MySQL database set up, you can skip to <u>Configuring and Starting the MySQL</u> Server on page 116 to verify that your MySQL configuration meets the requirements for Cloudera
- The datadir directory (/var/lib/mysql by default) must be located on a partition that has sufficient free space.
- 1. Install the MySQL database.

os	Command
RHEL	\$ sudo yum install mysql-server
SLES	\$ sudo zypper install mysql \$ sudo zypper install libmysqlclient_r15  Note: Some SLES systems encounter errors with the zypper install command. For more information, see the Novell Knowledgebase topic, error running chkconfig.
Ubuntu and Debian	\$ sudo apt-get install mysql-server

After issuing the command, you may need to confirm that you want to complete the installation.

#### Configuring and Starting the MySQL Server

- 1. Determine the version of MySQL.
- 2. Stop the MySQL server if it is running.

os	Command
RHEL	\$ sudo service mysqld stop
SLES, Ubuntu, and Debian	\$ sudo service mysql stop

- **3.** Move old InnoDB log files /var/lib/mysql/ib\_logfile0 and /var/lib/mysql/ib\_logfile1 from /var/lib/mysql/ to a backup location.
- **4.** Determine the location of the option file, my.cnf, and update it as follows::
  - To prevent deadlocks, set the isolation level to read committed.
  - Configure MySQL to use the InnoDB engine, rather than MyISAM. (The default storage engine for MySQL is MyISAM.) To check which engine your tables are using, run the following command from the MySQL shell:

```
mysql> show table status;
```

• To configure MySQL to use the InnoDB storage engine, add the following line to the [mysqld] section of the my.cnf option file:

```
[mysqld]
default-storage-engine = innodb
```

Binary logging is not a requirement for Cloudera Director installations. Binary logging provides benefits such
as MySQL replication or point-in-time incremental recovery after database restore. Examples of this
configuration follow. For more information, see <u>The Binary Log</u>.

Following is a typical option file:

```
[mysqld]
default-storage-engine = innodb
transaction-isolation = READ-COMMITTED
# Disabling symbolic-links is recommended to prevent assorted security risks;
# to do so, uncomment this line:
# symbolic-links = 0
key_buffer_size = 32M
max_allowed_packet = 32M
thread_stack = 256K
thread_cache_size = 64
query_cache_limit = 8M
query_cache_size = 64M
query_cache_type = 1
max\_connections = 550
#log_bin should be on a disk with enough free space. Replace
'/var/lib/mysql/mysql_binary_log' with an appropriate path for your system.
#log_bin=/var/lib/mysql/mysql_binary_log
#expire_logs_days = 10
#max_binlog_size = 100M
# For MySQL version 5.1.8 or higher. Comment out binlog_format for lower versions.
binlog_format = mixed
read_buffer_size = 2M
read_rnd_buffer_size = 16M
sort_buffer_size = 8M
join_buffer_size = 8M
# InnoDB settings
innodb_file_per_table = 1
```

```
innodb_flush_log_at_trx_commit = 2
innodb_log_buffer_size = 64M
innodb_buffer_pool_size = 4G
innodb_thread_concurrency = 8
innodb flush method = O DIRECT
innodb_log_file_size = 512M
[mysqld_safe]
log-error=/var/log/mysqld.log
pid-file=/var/run/mysqld/mysqld.pid
```

- 5. If AppArmor is running on the host where MySQL is installed, you might need to configure AppArmor to allow MySQL to write to the binary.
- **6.** Ensure that the MySQL server starts at boot.

os	Command	
RHEL	<pre>\$ sudo /sbin/chkconfig mysqld on \$ sudo /sbin/chkconfiglist mysqld mysqld     0:off 1:off 2:on 3:on 4:on 5:on 6:off</pre>	
SLES	\$ sudo chkconfigadd mysql	
Ubuntu and Debian	\$ sudo chkconfig mysql on  Note: chkconfig may not be available on recent Ubuntu releases. You may need to use Upstart to configure MySQL to start automatically when the system boots. For more information, see the Ubuntu documentation or the Upstart Cookbook.	

7. Start the MySQL server:

os	Command
RHEL	\$ sudo service mysqld start
SLES, Ubuntu, and Debian	\$ sudo service mysql start

8. Set the MySQL root password. In the following example, the current root password is blank. Press the Enter key when you're prompted for the root password.

```
$ sudo /usr/bin/mysql_secure_installation
Enter current password for root (enter for none):
OK, successfully used password, moving on...
[...]
Set root password? [Y/n] y
New password:
Re-enter new password:
Remove anonymous users? [Y/n] Y
[...]
Disallow root login remotely? [Y/n] N
[...]
Remove test database and access to it [Y/n] Y
[...]
Reload privilege tables now? [Y/n] Y
All done!
```

## Installing the MySQL JDBC Driver

Install the MySQL JDBC driver for the Linux distribution you are using.

OS	Command
RHEL 5 or 6	1. Download the MySQL JDBC driver from the Download Connector/J page of the MySQL web site.  2. Extract the JDBC driver JAR file from the downloaded file. For example:  tar zxvf mysql-connector-java-version.tar.gz  3. Add the JDBC driver, renamed, to the relevant server. For example:  \$ sudo cp
SLES	\$ sudo zypper install mysql-connector-java
Ubuntu or Debian	\$ sudo apt-get install libmysql-java

## Creating a Database for Cloudera Director Server

You can create the database on the host where the Cloudera Director server will run, or on another host that is accessible by the Cloudera Director server. The database must be configured to support UTF-8 character set encoding.

Record the values you enter for database names, usernames, and passwords. Cloudera Director requires this information to connect to the database.

**1.** Log into MySQL as the root user:

```
$ mysql -u root -p
Enter password:
```

2. Create a database for Cloudera Director server:

```
mysql> create database database DEFAULT CHARACTER SET utf8;
Query OK, 1 row affected (0.00 sec)
mysql > grant all on database.* TO 'user'@'%' IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.00 sec)
```

database, user, and password can be any value. The examples match the names you provide in the Cloudera Director configuration settings described below in <u>Configure Cloudera Director Server to use the MySQL Database</u>.

#### Backing Up MySQL Databases

To back up the MySQL database, run the mysqldump command on the MySQL host, as follows:

```
$ mysqldump -hhostname -uusername -ppassword database > /tmp/database-backup.sql
```

## Configuring Cloudera Director Server to use the MySQL Database

Before starting the Cloudera Director server, edit the "Configurations for database connectivity" section of /etc/cloudera-director-server/application.properties.

Note: If the Cloudera Director server is already running, it must be restarted after configuring MySQL access. The server will not load configuration updates while running.

```
# Configurations for database connectivity.
# Optional database type (H2 or MySQL) (defaults to H2)
#lp.database.type: mysql
# Optional database username (defaults to "director")
#lp.database.username:
# Optional database password (defaults to "password")
#lp.database.password:
# Optional database host (defaults to "localhost")
#lp.database.host:
# Optional database port (defaults to 3306)
#lp.database.port:
# Optional database (schema) name (defaults to "director")
#lp.database.name:
```

## Migrating Cloudera Director Server from H2 to MySQL

If you are already running Cloudera Director with an embedded H2 database, you can migrate to a MySQL database by following the steps in this section. The SQL dialect that H2 uses is not compatible with MySQL, so this process requires the use of SQuirreL SQL, which translates the SQL dialect of H2 into that of MySQL. Cloudera Director will be used to create the schema in the MySQL database because SQuirrel SQL's translation will not create the database schema exactly as Cloudera Director requires.

Note: Cloudera strongly recommends using MySQL or MariaDB for production deployments of Cloudera Director, instead of H2.

#### Step 1: Preparation of databases

- 1. Stop Cloudera Director and back up the H2 database file, state.h2.db. The H2 database file is located at /var/lib/cloudera-director-server/state.h2.db.
- **2.** Create a user on the MySQL server for Cloudera Director:

```
CREATE USER director IDENTIFIED BY password;
```

## Configuring Storage for Cloudera Director

**3.** Create a database on the MySQL server for exporting the data from H2:

```
CREATE DATABASE directorexport CHARACTER SET utf8;
GRANT ALL PRIVILEGES ON directorexport.* TO 'director'@'%';
```

**4.** Create a database on the MySQL server for use by Cloudera Director:

```
CREATE DATABASE director CHARACTER SET utf8;
GRANT ALL PRIVILEGES ON director.* TO 'director'@'%';
```

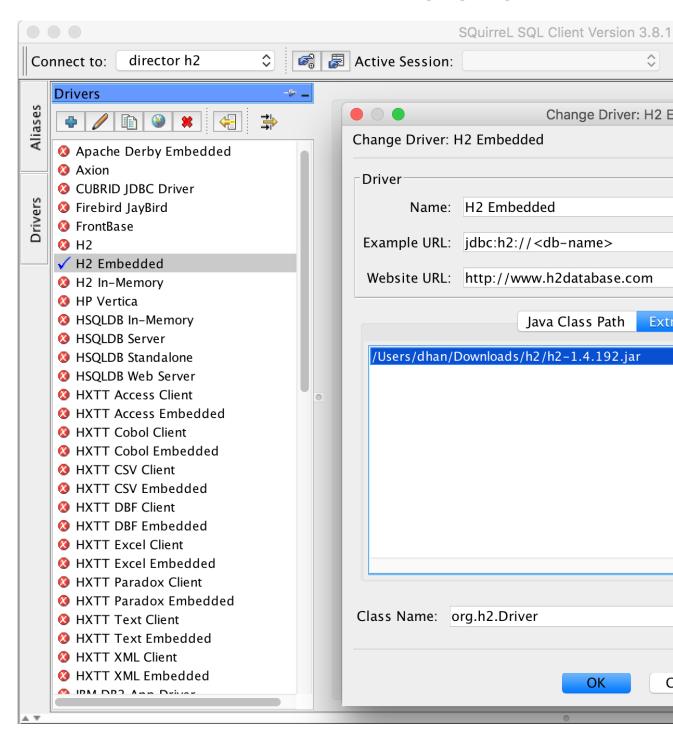

## Step 2: Export data from H2 database

1. Install SQuirreL SQL.

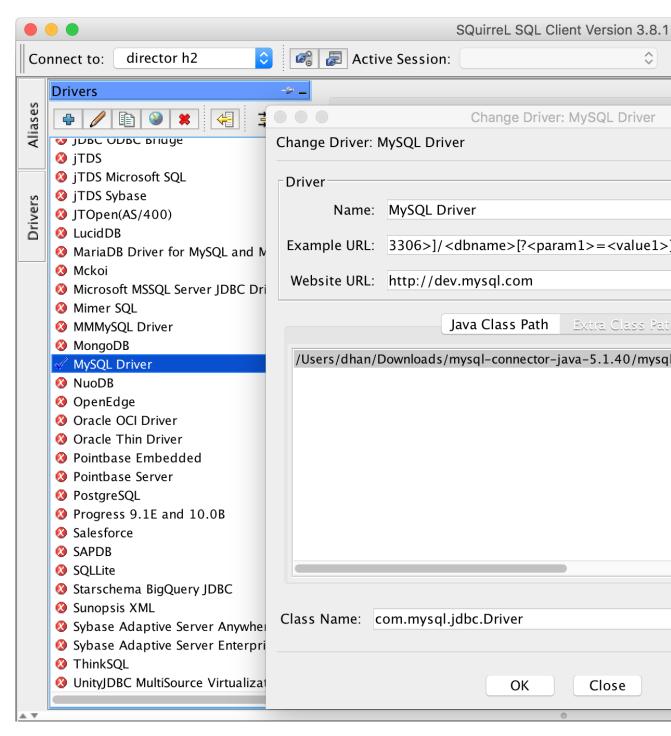

Note: H2, MySQL, and SQuirreL SQL can be run on different nodes.

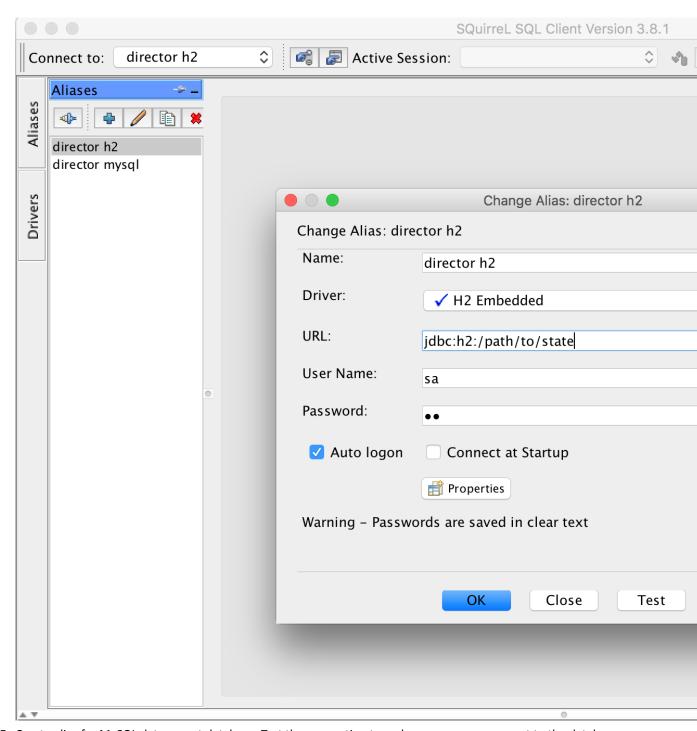

- a. Download SQuirreL SQL from the SQuirreL SQL web site.
- **b.** Install SQuirreL SQL with the H2 and MySQL database plugins enabled.
- 2. Enable the H2 Embedded driver in SQuirreL SQL.
  - a. Download H2 from <a href="http://www.h2database.com/html/download.html">http://www.h2database.com/html/download.html</a>.
  - **b.** Edit the **H2 Embedded** driver, adding the downloaded jar file to the **Extra Class Path**.

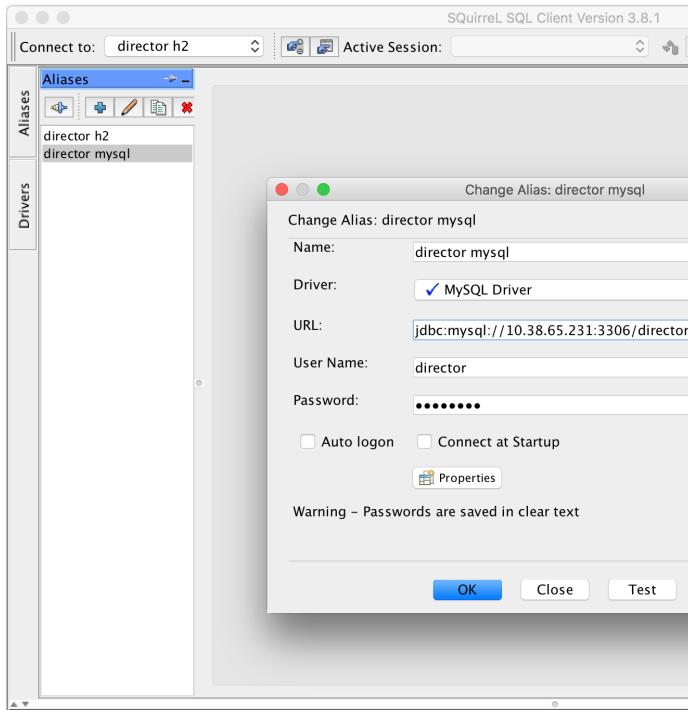

- 3. Enable the "MySQL Driver" driver in SQuirreL SQL.
  - a. Download the MySQL driver from the MySQL Downloads site.
  - **b.** Edit the "MySQL Driver" driver, adding the MySQL connector jar to the Extra Class Path.

4. Create an alias for the H2 database. Test the connection to make sure you can connect to the database.

5. Create alias for MySQL data export database. Test the connection to make sure you can connect to the database.

**6.** Prepare the H2 database for data export. H2 generates names for indexes that are longer than what is permitted in MySQL, so you must rename the indexes in H2 to ensure that they do not violate the MySQL length limit. For example:

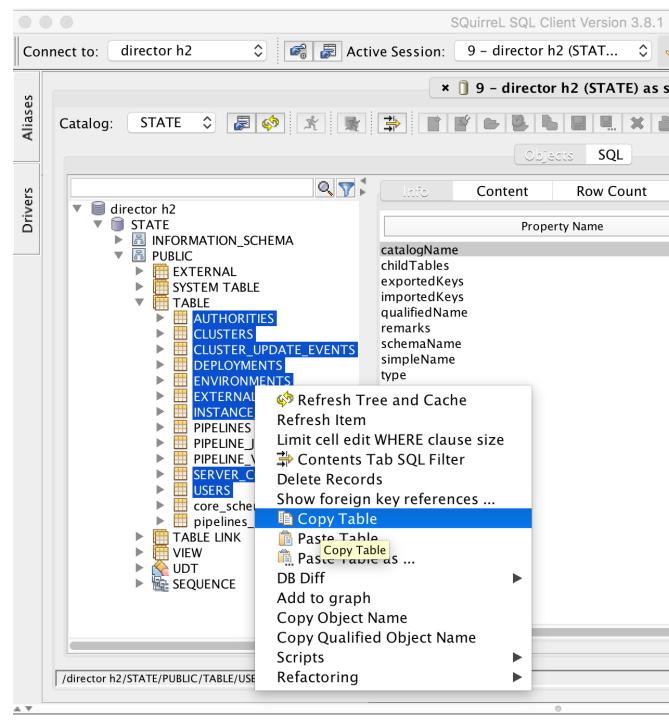

ALTER INDEX DEPLOYMENTS\_UNIQUE\_PER\_ENVIRONMENT\_BY\_DEPLOYMENT\_NAME\_INDEX\_8 RENAME TO DEPLOYMENTS\_UNIQUE\_PER\_ENVIRONMENT\_BY\_DEPLOYMENT\_NAME ALTER INDEX UK\_EXTERNAL\_DATABASE\_SERVERS\_UNIQUE\_PER\_ENVIRONMENT\_BY\_NAME\_INDEX\_8 RENAME TO UK\_EXTERNAL\_DATABASE\_SERVERS\_UNIQUE\_PER\_ENVIRONMENT\_BY\_NAME

**Note:** Scroll to the right to see the entire lines in the above code sample.

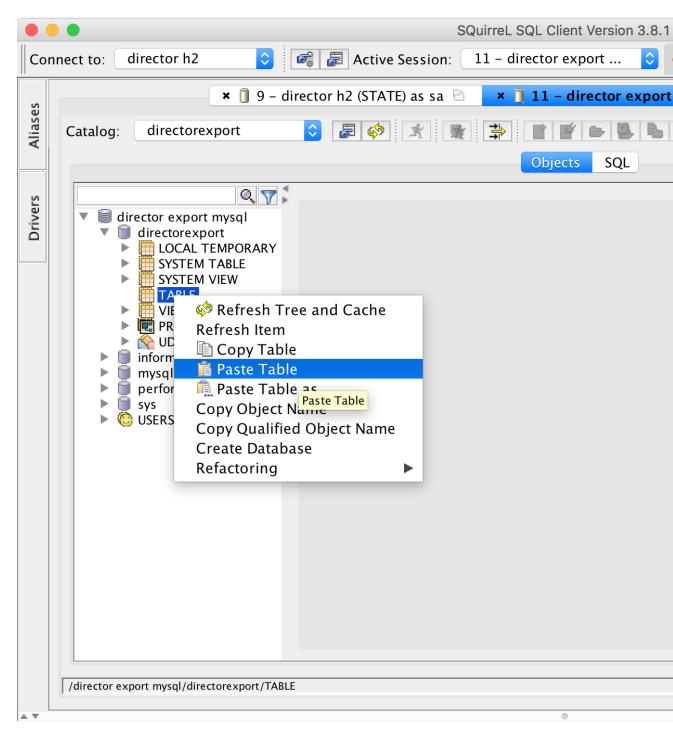

- 7. Prepare MySQL for data export.
  - a. Depending on the Cloudera Director and MySQL versions you are running, you might need the following step. If you see the error message invalid default value after performing the next step, you need to do this. Otherwise, this step is optional.

```
select @@global.sql_mode
// Keep the value somewhere if you would like to restore the value
// at the end of this procedure. (See step 9c below.)
set @@global.sql_mode = "...";
// remove NO_ZERO_IN_DATE,NO_ZERO_DATE from previous value.
```

- **b.** Reconnect to the MySQL alias for this change to apply to your session.
- 8. Export data from H2 to MySQL.
  - a. Go to the Alias pane in SQuirreL SQL, and connect to H2.
  - b. Go to h2 > STATE > PUBLIC > TABLE. Select all tables except for the PIPELINES\* and \*schema\_versions tables, right click and select Copy Table.

- c. Go to the Alias pane in SQuirreL SQL and connect to MySQL.
- **d.** Go to **mysql** > **directorexport** > **TABLE**, right click **TABLE** and select **Paste Table**.

9. Restore sql mode, if desired (for more about sql mode, see Prepare MySQL for data export above).

## Step 3: Prepare MySQL database for data import

Start Cloudera Director with MySQL.

- 1. Configure Cloudera Director to use MySQL, as described in Configuring Cloudera Director Server to use the MySQL Database on page 119.
- 2. Start Cloudera Director with MySQL. When Cloudera Director starts, the database schema will be created.
- 3. Stop Cloudera Director to prevent modification of the database during data import.

#### Configuring Storage for Cloudera Director

4. Delete all values from the AUTHORITIES, USERS, and SERVER CONFIGS tables. Cloudera Director populates these tables with some values by default. These values should be deleted so they will not conflict with the imported data.

```
DELETE FROM AUTHORITIES;
DELETE FROM USERS;
DELETE FROM SERVER_CONFIGS;
```

#### Step 4: Import data to MySQL

1. Dump the data only (no schema) from the export database. You can use the -h option if running mysqldump against a remote host.

```
$ mysqldump -u [user] -p --no-create-info directorexport > directorexport.sql
```

2. Import the data into Cloudera Director's database. You may use the -h option if running mysql against a remote host.

```
$ mysql -u [user] -p director < directorexport.sql</pre>
```

# Using MariaDB for Cloudera Director Server

Note: This section is about the data Cloudera Director server stores for its own use. You can also use external databases for Cloudera Manager and cluster services. For more information, see <u>Using an</u> External Database for Cloudera Manager and CDH on page 136.

Note: For information on configuring Cloudera Director and the MariaDB database to communicate using TLS, see Enabling TLS with Cloudera Director, and especially the section, TLS for Cloudera Director's Database on page 162.

Cloudera Director stores various kinds of data, including information about deployments, database servers, users, CDH clusters, and Cloudera Manager instances. By default, this data is stored in an embedded H2 database stored on the filesystem where the server is running at the following location:

```
/var/lib/cloudera-director-server/state.h2.db
```

Alternatively, you can use a MariaDB database instead of the embedded H2 database, as described below.

## Installing the MariaDB Server

#### Note:

- If you already have a MariaDB database set up, you can skip to Configuring and Starting the MariaDB Server on page 129 to verify that your MariaDB configuration meets the requirements for Cloudera Director.
- The datadir directory (/var/lib/mysql by default) must be located on a partition that has sufficient free space.
- 1. Install the MariaDB database.

```
$ sudo yum install mariadb-server
```

After issuing the command, you might need to confirm that you want to complete the installation.

## Configuring and Starting the MariaDB Server

- 1. Stop the MariaDB server if it is running.
  - For RHEL 6:

```
$ sudo service mariadb stop
```

• For RHEL 7:

```
$ sudo systemctl mariadb stop
```

- $\textbf{2. Move old InnoDB log files } / \texttt{var/lib/mysql/ib\_logfile0 and } / \texttt{var/lib/mysql/ib\_logfile1 from } \\$ /var/lib/mysql/ to a backup location.
- 3. Determine the location of the option file, my.cnf, and update it as follows::
  - To prevent deadlocks, set the isolation level to read committed.
  - Configure MariaDB to use the InnoDB engine, rather than MyISAM. (The default storage engine for MariaDB is MyISAM.) To check which engine your tables are using, run the following command from the MariaDB shell:

```
mysql> show table status;
```

 To configure MariaDB to use the InnoDB storage engine, add the following line to the [mysqld] section of the my.cnf option file:

```
[mysqld]
default-storage-engine = innodb
```

 Binary logging is not a requirement for Cloudera Director installations. Binary logging provides benefits such as MariaDB replication or point-in-time incremental recovery after database restore. Examples of this configuration follow. For more information, see The Binary Log.

Following is a typical option file:

```
[mysqld]
default-storage-engine = innodb
transaction-isolation = READ-COMMITTED
# Disabling symbolic-links is recommended to prevent assorted security risks;
# to do so, uncomment this line:
# symbolic-links = 0
key_buffer_size = 32M
max_allowed_packet = 32M
thread_stack = 256K
thread cache size = 64
query_cache_limit = 8M
query_cache_size = 64M
query_cache_type = 1
max connections = 550
#log_bin should be on a disk with enough free space. Replace
'/var/lib/mysql/mysql_binary_log' with an appropriate path for your system.
#log_bin=/var/lib/mysql/mysql_binary_log
#expire_logs_days = 10
#max_binlog_size = 100M
# For MySQL version 5.1.8 or later. Comment out binlog_format for older versions.
binlog_format = mixed
read_buffer_size = 2M
read rnd buffer size = 16M
sort_buffer_size = 8M
join_buffer_size = 8M
```

#### Configuring Storage for Cloudera Director

```
# InnoDB settings
innodb_file_per_table = 1
innodb_flush_log_at_trx_commit = 2
innodb_log_buffer_size = 64M
innodb_buffer_pool_size = 4G
innodb_thread_concurrency = 8
innodb_flush_method = O_DIRECT
innodb_log_file_size = 512M

[mysqld_safe]
log-error=/var/log/mysqld.log
pid-file=/var/run/mysqld/mysqld.pid
```

- **4.** If AppArmor is running on the host where MariaDB is installed, you might need to configure AppArmor to allow MariaDB to write to the binary.
- **5.** Ensure the MariaDB server starts at boot.
  - For RHEL 6:

```
$ sudo chkconfig mysqld on
```

• For RHEL 7:

```
$ sudo systemctl enable mariadb
```

- 6. Start the MariaDB server:
  - For RHEL 6:

```
$ sudo service mysqld start
```

• For RHEL 7:

```
$ sudo systemctl mariadb start
```

7. Set the MariaDB root password. In the following example, the current root password is blank. Press the **Enter** key when you're prompted for the root password.

```
$ sudo /usr/bin/mysql_secure_installation
[...]
Enter current password for root (enter for none):
OK, successfully used password, moving on...
[...]
Set root password? [Y/n] y
New password:
Re-enter new password:
Remove anonymous users? [Y/n] Y
[...]
Disallow root login remotely? [Y/n] N
[...]
Remove test database and access to it [Y/n] Y
[...]
Reload privilege tables now? [Y/n] Y
All done!
```

#### Installing the MariaDB JDBC Driver

Install the MariaDB JDBC driver for the Linux distribution you are using.

**Note:** The JDBC driver described here to use for MariaDB is the MySQL driver, which works with MariaDB, as well.

- Download the MySQL JDBC driver from <a href="http://www.mysgl.com/downloads/connector/j/5.1.html">http://www.mysgl.com/downloads/connector/j/5.1.html</a>.
- **2.** Extract the JDBC driver JAR file from the downloaded file. For example:

```
tar zxvf mysql-connector-java-5.1.31.tar.gz
```

**3.** Copy the JDBC driver, renamed, to the relevant host. For example:

```
$ sudo cp mysql-connector-java-5.1.31/mysql-connector-java-5.1.31-bin.jar
/usr/share/java/mysql-connector-java.jar
```

If the target directory does not yet exist on this host, you can create it before copying the JAR file. For example:

```
$ sudo mkdir -p /usr/share/java/
$ sudo cp mysql-connector-java-5.1.31/mysql-connector-java-5.1.31-bin.jar
/usr/share/java/mysql-connector-java.jar
```

Note: Do not use the yum install command to install the MySQL driver package, because it installs openJDK, and then uses the Linux alternatives command to set the system JDK to be openJDK.

## Creating a Database for Cloudera Director Server

You can create the database on the host where the Cloudera Director server will run, or on another host that is accessible by the Cloudera Director server. The database must be configured to support UTF-8 character set encoding.

Record the values you enter for database names, usernames, and passwords. Cloudera Director requires this information to connect to the database.

**1.** Log into MariaDB as the root user:

```
$ mysql -u root -p
Enter password:
```

2. Create a database for Cloudera Director server:

```
mysql> create database database DEFAULT CHARACTER SET utf8;
Query OK, 1 row affected (0.00 sec)
mysql > grant all on database.* TO 'user'@'%' IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.00 sec)
```

database, user, and password can be any value. The examples match the names you provide in the Cloudera Director configuration settings described below in Configure Cloudera Director Server to use the MariaDB Database.

#### Backing Up MariaDB Databases

To back up the MariaDB database, run the <code>mysqldump</code> command on the MariaDB host, as follows:

```
$ mysqldump -hhostname -uusername -ppassword database > /tmp/database-backup.sql
```

## Configuring Cloudera Director Server to use the MariaDB Database

Before starting the Cloudera Director server, edit the "Configurations for database connectivity" section of /etc/cloudera-director-server/application.properties.

**Note:** If the Cloudera Director server is already running, it must be restarted after configuring MariaDB access. The server will not load configuration updates while running.

```
# Configurations for database connectivity.
# Optional database type (h2 or mysql) (defaults to h2)
#lp.database.type: mysql
# Optional database username (defaults to "director")
#lp.database.username:
# Optional database password (defaults to "password")
#lp.database.password:
# Optional database host (defaults to "localhost")
#lp.database.host:
# Optional database port (defaults to 3306)
#lp.database.port:
# Optional database (schema) name (defaults to "director")
#lp.database.name:
```

# Cloudera Director Database Encryption

The Cloudera Director server stores sensitive data in its database, including SSH credentials and cloud provider keys. You can configure Cloudera Director to encrypt the data stored in the Cloudera Director database.

Note: This section discusses data stored in the Cloudera Director database, not data stored in databases used by Cloudera Manager or CDH cluster services.

## Cipher Configuration

Database encryption is configured by setting the two server configuration properties described in the following table.

**Table 3: Server Configuration Properties** 

Property	Description	
lp.encryption.twoWayCipher	Cipher used to encrypt data. Possible values:	
	<ul> <li>desede - Triple DES (default)</li> <li>passthrough - No encryption</li> <li>transitional - Changing encryption</li> </ul>	
Ip.encryption.twoWayCipherConfig	The configuration string for the chosen cipher.	

The format of the configuration string varies with the choice of cipher, as described in the table below:

**Table 4: Ciphers and Configuration Strings** 

Cipher	Configuration String Format
desede	24-byte symmetric encryption key, encoded as a string using Base64
passthrough	ignored
transitional	combination of old cipher and new cipher (see below)

The default value for the configuration string is a fixed 24-byte key for the default triple DES encryption:

ZGVmYXVsdGRpcmVjdG9yZGVzZWRla2V5

Important: Cloudera highly recommends that you configure a different triple DES key. A warning appears in the server log if the default key is detected.

## Starting with Encryption

Cloudera Director's default configuration for database encryption encrypts new data stored in the Cloudera Director database. This default configuration uses triple DES encryption, with a default key, to protect data. In a new installation of Cloudera Director, all data needing protection will be encrypted under the default encryption scheme. In an installation that was previously not configured for encryption, including older releases of Cloudera Director, new data needing protection will be encrypted, but old data needing protection will remain unencrypted until it is updated in the database over time.

If this level of protection is sufficient for your needs, it is not necessary to make any changes to Cloudera Director configuration. While Cloudera Director will function correctly, keep in mind that there are drawbacks: some data needing protection in the database may remain unencrypted indefinitely, and data that is encrypted is effectively only obscured, since the default key is not secret.

#### Establishing More Secure Encryption for New Installations

For a new installation of Cloudera Director, Cloudera recommends that you generate and configure your own secret encryption key, different from the default key. Create a new key by generating 24 bytes of random data from a cryptographically secure random generator, and encode the bytes using the Base64 encoding algorithm.

Here is an example of generating a new key using Python.

```
python -c 'import base64, os; print base64.b64encode(os.urandom(24))'
```

Set the Cloudera Director configuration property lp.encryption.twoWayCipherConfig to the Base64-encoded key string before starting Cloudera Director for the first time. All data needing protection in the database will be encrypted with this key. It is good practice to change the encryption key periodically to protect against unintentional disclosure. See Changing Encryption below for more.

Note: If you configure a new secret key, Cloudera recommends you restrict permissions on the configuration file (application.properties) to protect the key from disclosure. Ensure that at least the user running Cloudera Director can still read the file.

### Establishing More Secure Encryption for Existing Installations

For an existing installation of Cloudera Director that uses either no encryption at all (including older releases of Cloudera Director) or uses only the default encryption, Cloudera recommends that you use a transitional cipher to change encryption to a more secure state. Not only will changing encryption introduce the use of a non-default and secret key, but it will also forcibly encrypt all data needing protection in the database, whether it was already encrypted or not.

See Changing Encryption below for details on how to configure a transitional cipher to change encryption. When configuring the transitional cipher, you will need to know information about the old cipher that was in effect.

- If the default cipher and key was in use previously, then use "desede" and the default key for the old cipher configuration.
- · If no encryption was in place previously, including older releases of Cloudera Director which did not support database encryption, then use "passthrough" (with no configuration string) for the old cipher configuration.

The new cipher should be triple DES ("desede") with a secret key that you generate. See Establishing More Secure Encryption for New Installations above for details on how to generate a good key.

## Configuring Storage for Cloudera Director

After establishing more secure encryption, it is good practice to change the encryption key periodically to protect against unintentional disclosure. Use the transitional cipher again to change encryption to use a new key.

## **Changing Encryption**

To change the key used for database encryption, or change to a different cipher, you must configure the Cloudera Director server to use a transitional cipher.

Note: Transitional ciphers are supported for Cloudera Director server only, not for Cloudera Director client.

If a transitional cipher is configured, Cloudera Director encrypts all data that needs protection, changing from an old encryption scheme to a new encryption scheme. A transitional cipher can change the encryption in effect, or introduce it when it has not been used before, including under older Cloudera Director releases. It also ensures that all data needing protection becomes encrypted.

To configure a transitional cipher:

- 1. Stop the server.
- 2. Configure lp.encryption.twoWayCipher with the value transitional.
- 3. Configure lp.encryption.twoWayCipherConfig with a configuration string describing both the old cipher and the new cipher.
- **4.** Start the server.

The configuration string for a transitional cipher has the following format:

old-cipher;old-configuration-string new-cipher;new-configuration-string

For example, to change the triple DES key, use a configuration string like this:

desede;old-key-in-base64|desede;new-key-in-base64

To transition from the default triple DES encryption key to a new key, use a configuration string like this:

desede; ZGVmYXVsdGRpcmVjdG9yZGVzZWRla2V5 | desede; new-key-in-base64

To transition from no encryption to triple DES encryption with a new key, use a configuration string like this:

passthrough; desede; new-key-in-base64

A transitional cipher cannot be used as the old or new cipher in another transitional cipher.

When the server restarts, it detects that a transitional cipher is configured and updates all relevant data, unencrypted and encrypted, to the new cipher. After this process is complete, the server continues startup as usual. Configuring a transitional cipher ensures that all data needing protection in the database is encrypted.

#### Wait for the Server to Complete Ongoing Work

Do not try to change encryption while the server is performer ongoing work. If any work is waiting to be resumed by the server on startup (for example, bootstrapping a new cluster), then the server will refuse to change encryption and will stop. If this happens, you must configure the server for its old cipher, start it, and wait for that work to resume and be completed.

### Changing from a Transitional Cipher to a Normal Cipher

After encryption has been changed using a transitional cipher, you can configure the server to use the new cipher normally.

**Example:** Assume the configuration string for the transitional cipher was as follows:

desede;old-key-in-base64|desede;new-key-in-base64

One restart of the server will suffice to pick up this change, and then the following configuration string for a normal cipher can be used:

desede; new-key-in-base64

Cloudera recommends that the server be left to run with a transitional cipher only until its next restart or upgrade, and then be reconfigured to use a normal cipher. There are two reasons for doing this:

- While configured with a transitional cipher, the server will not restart if work is waiting to be resumed.
- If the server is left configured with a transitional cipher, each time it is restarted the database contents will be re-encrypted using the same key.

# Configuring Storage for Cloudera Manager and CDH

This section explains options for configuring storage for Cloudera Manager and CDH. Options include the following:

- Use of an external database for Cloudera Manager and CDH in place of the embedded H2 database.
- Object storage for use by Cloudera Director, Cloudera Manager, and CDH clusters:
  - Amazon S3 object storage
  - Microsoft Azure ADLS object storage
- Using AWS EBS volumes for block storage in AWS

# Using an External Database for Cloudera Manager and CDH

By default, Cloudera Director configures Cloudera Manager and CDH services, such as Hive, to use the Cloudera Manager embedded PostgreSQL database. You can use Cloudera Director to configure them to use external database servers, instead, which is recommended for production environments. If you have a database server already configured, you can configure Cloudera Manager and CDH services to create or use databases on that server. You can also configure Cloudera Director to use a cloud provider service such as Amazon's Relational Database Service (RDS) to provision new database servers.

You can also configure Cloudera Manager and CDH services to use Amazon Elastic Block Store (EBS) volumes, as described in <u>Using EBS Volumes for Cloudera Manager and CDH</u> on page 145.

How you set up external database servers and databases differs depending on whether you are using Cloudera Director client or Cloudera Director server:

- Cloudera Director client Configure external databases in the cluster.conf file and launch Cloudera Director client (standalone) by issuing the bootstrap command.
- Cloudera Director server Configure external databases for Cloudera Director server in one of the following ways:
  - Using the Cloudera Director web UI
  - Using the Cloudera Director REST API
  - By editing the cluster.conf file and launching the Cloudera Director server with the bootstrap-remote

The topics in this section describe how to use Cloudera Director to define external database servers and external databases.

#### **Defining External Database Servers**

Cloudera Director needs information about external database servers before it can use them. This section describes defining database server templates and using Amazon Relational Database Service (RDS) to create new database servers..

#### The Database Server Template

A database server template can refer to either an existing database server or a server to be created. The following are the basic elements of a database server template:

- name A unique name for the server within the environment
- type The type of database server, such as "MYSQL" or "POSTGRESQL"
- hostname The name of the server host
- **port** The listening port of the server
- username The name of the administrative account for the server
- password The password for the administrative account

The hostname and port are optional in a template. If they are not present, Cloudera Director assumes that the template refers to a server that does not yet exist and must be created.

A database server template also supports a table of key-value pairs of configuration information, which Cloudera Director may require when creating a new server. A template also supports a second table of tag data, which Cloudera Director can employ for certain cloud providers, including Amazon Web Services.

Note: A single database server is scoped to an environment, so only deployments and clusters in that environment recognize it.

#### Defining a Database Server Using the API

The Cloudera Director server has a REST service endpoint for managing external database server definitions. The operations supported by the endpoint are described in the table below.

- Each service URI begins with "/api/v9/environments/{environment}", where "{environment}" is the name of the environment within which the database server definition is scoped.
- They all use JSON for input data and response data.

Operation	Description	Notes
POST /databaseServers/	Define a new database.	Admin required.
GET /databaseServers/	List all database servers.	
DELETE /databaseServers/{name}	Delete a database server definition.	Admin required.
PUT /databaseServers/{name}	Update a database server definition.	Admin required.
GET /databaseServers/{name}	Get a database server definition.	
GET /databaseServers/{name}/status	Get the status of a database server.	
GET /databaseServers/{name}/template	Get the template from which a database server was defined.	

If a database server template without a host and port is posted to Cloudera Director, Cloudera Director will asynchronously begin the process of creating the server on a cloud provider. The provider is selected based on the environment.

Similarly, if a database server definition is deleted, and the server was originally created by Cloudera Director, Cloudera Director will begin the process of deleting the database from the cloud provider. Before deleting a server definition, be sure to make any backups of the server that you need.

The status of a database server indicates its current position in the server lifecycle. The following values can be returned by the GET database server status operation:

Status	Description
BOOTSTRAPPING	Cloudera Director is in the process of creating the server.
BOOTSTRAP_FAILED	Cloudera Director failed to create the server.
READY	The server is available for use.
TERMINATING	Cloudera Director is in the process of destroying the server.
TERMINATE_FAILED	Cloudera Director failed to terminate the server.
TERMINATED	The server has been destroyed.

#### Defining a Database Server Using the Client Configuration File

Database server templates can be provided in the configuration file passed to the Cloudera Director standalone client. Define external database servers in the databaseServers section of a configuration file.

See the API section above for a description of the different parts of a template. The following example defines two existing database servers.

```
databaseServers {
   mysql1 {
      type: mysql
      host: 1.2.3.4
      port: 3306
      user: root
      password: password
   postgres1 {
      type: postgresql
      host: 1.2.3.4
      port: 5432
      user: postgres
      password: password
}
```

The following example defines a server that Cloudera Director must create using RDS.

```
databaseServers {
   mysqlt1 {
      type: mysql
      user: root
      password: password
      instanceClass: db.m3.medium
      engineVersion: 5.5.40b
      dbSubnetGroupName: default
      vpcSecurityGroupIds: sq-abcd1234
      allocatedStorage: 10
      tags {
         owner: jsmith
   }
}
```

You cannot include both existing servers and servers that Cloudera Director must create, in the same configuration file. You can create new database servers separately in a cloud provider and then define them as existing servers in the configuration file.

#### Using Amazon RDS for External Databases

Cloudera Director can use Amazon Relational Database Service (RDS) to create new database servers. These servers can be used to host external databases for Cloudera Manager and CDH cluster services.

#### Note:

- Currently, only MySQL 5.6 and 5.7 RDS instances are supported.
- RDS works through both bootstrap-remote and standalone bootstrap on the client, as well as through the web UI and the server API.
- The database server must be in the same AWS region as Cloudera Director.
- Storage encryption for RDS instances is not supported in Cloudera Director 2.1.x and lower. Storage encryption is supported in Cloudera Director 2.2 and higher, using the default key ID associated with RDS for the AWS account. Use of a nondefault KMS key is not supported.

To enable storage encryption for a new RDS instance, check the Encrypt DB Instance checkbox in the web UI, or include storageEncrypted: true for the instance template in a Cloudera Director configuration file.

#### Creating a Template to Use Amazon RDS as an External Database

To define an external database server to be created on RDS, you use a template just as you would for any other server. However, you do notspecify the host and port; these are determined as the server is created.

- **name** A unique name for the server in the environment
- type The type of database server, such as "MYSQL"
- username The name of the administrative account for the server
- password The password for the administrative account

The key-value configuration information in the template for an RDS server must include information required by RDS to create a new instance. Cloudera recommends that you specify the engine version in a template. If you do not specify the version, RDS defaults to a recent version, which can change over time.

Note: If you are including Hive in your clusters, and you configure the Hive metastore to be installed on MySQL through RDS, Cloudera Manager may report that "The Hive Metastore canary failed to create a database." This is caused by a MySQL bug that is exposed when using MySQL 5.6.5 or higher with the MySQL JDBC driver (used by Cloudera Director) version 5.1.19 or lower. Cloudera recommends that you use a MySQL version that avoids revealing this bug for the driver version installed by Cloudera Director from your platform software repositories.

Кеу	Description	Example
instanceClass	Instance type for the database server instance	db.m3.medium
dbSubnetGroupName	Name of the database subnet group that the instance spans	default
engineVersion	(optional) Version of the database engine	5.5.40b
vpcSecurityGroupIds	Comma-separated list of security groups for the new instance	sg-abc123,sg-def456
allocatedStorage	Storage in gigabytes for the new server	10
availabilityZone	(optional) Preferred availability zone for the new server	us-east-1d
backupRetentionPeriod	Number of days for which automated backups are retained (0 to disable)	30
skipFinalSnapshot	Whether to skip a final snapshot before the instance is deleted (true to skip; otherwise false)	false
storageEncrypted	Whether stored data on RDS instances is encrypted (true to encrypt; otherwise false)	true

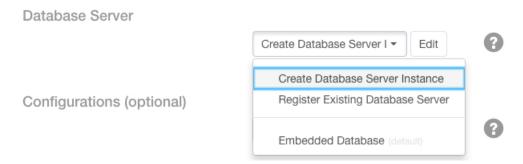

**Note:** The template can also specify tags for the new instance.

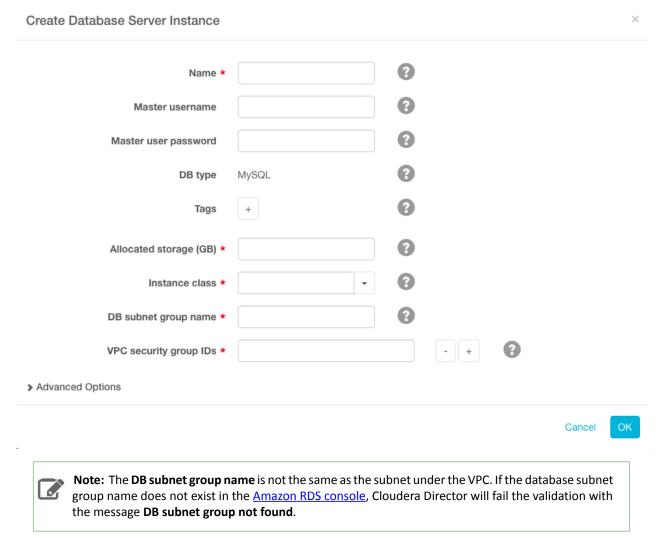

#### Defining a Database Server in AWS Using RDS: Web UI

You can define an RDS database in AWS using the Cloudera Director web UI when you create a Cloudera Manager instance. In the Database Server section near the top of the Add Cloudera Manager wizard, click the dropdown list and select either Create Database Server Instance or Register Existing Database Server:

#### Configuring Storage for Cloudera Manager and CDH

Select Create Database Server Instance to create a new MySQL database server with RDS. In the Create Database Server Instance window, enter credentials and configuration values for the database server:

For more information about configuring a database in Amazon RDS, see the Amazon Relational Database Service Documentation.

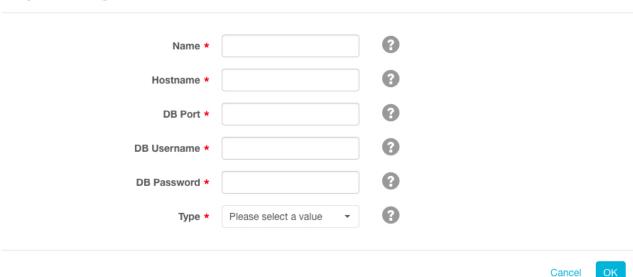

Note: Cloudera Director also supports PostgreSQL database servers for Cloudera Manager and CDH, but you must create them outside of Cloudera Director and then treat them as existing databases by selecting Register Existing Database Server.

Select Register Existing Database Server to use an existing MySQL or PostgreSQL database server. In the Register Existing Database Server window, enter information and credentials about your existing database server.

×

#### Register Existing Database Server

## Defining a Database Server in AWS Using RDS: API

Use the previously described REST service endpoint for external database server definitions to create and destroy external database servers using RDS. The environment in which servers are defined must already be configured to use AWS, and your account must have permission to create and delete RDS instances.

When an external database server template is submitted through POST to the endpoint, and the template lacks a host and port, Cloudera Director accepts the definition for the server and asynchronously begins the process of creating the new server. The complete existing server definition, including the host and port, are eventually available through

Likewise, when the definition is deleted using DELETE, Cloudera Director begins destroying the server.

While a new server is being created on RDS, you can begin bootstrapping new deployments and new clusters that have external database templates that refer to the server. The bootstrap process proceeds in tandem with the server creation, and pauses when necessary to wait for the new RDS instance to be available.

When a deployment or cluster is terminated, Cloudera Director does not terminate the RDS instances. As a result, multiple deployments and clusters can share the same external database servers that Cloudera Director creates on RDS.

### Defining a Database Server in AWS Using RDS: Client Configuration File

The following example defines a server that Cloudera Director creates using RDS:

```
databaseServers {
   mysqlt1 {
      type: mysql
      user: root
      password: password
      instanceClass: db.m3.medium
      engineVersion: 5.5.40b
      dbSubnetGroupName: default
      vpcSecurityGroupIds: sg-abcd1234
      allocatedStorage: 10
      tags {
         owner: jsmith
}
```

The following example of an external database template uses the new server that Cloudera Director creates. The databaseServerName item matches the name of the new server:

```
cluster
   #... databaseTemplates: {
   HIVE {
        name: hivetemplate
        databaseServerName: mysqlt1
        databaseNamePrefix: hivemetastore
        usernamePrefix: hive
   }
}
```

## **Defining External Databases**

After external database servers are defined, the databases on them can be defined. Cloudera Director can use databases that already exist on those servers, or it can create them while bootstrapping new Cloudera Manager instances or CDH clusters.

The following parts of an existing database must be defined:

- type The type of database, "MYSQL" or "POSTGRESQL."
- hostname The name of the server host.
- port The listening port of the server.
- name The name of the database on the server.
- **username** The name of the user account having full access to the database.
- password The password for the user account.

The parts of an external database template are:

- name A unique name for the template within the deployment or cluster template.
- databaseServerName The name of the external database server where the new database is to reside.
- databaseNamePrefix The string prefix for the name of the new database server.
- usernamePrefix The string prefix for the name of the new user account that will have full access to the database.

The database server name in a database server template must refer to an external database server that is already defined.

When Cloudera Director creates the new database, it names the database by starting with the prefix in the template and then appends a random string. This prevents name duplication issues when sharing a database server across many deployments and clusters. Likewise, Cloudera Director creates new user accounts by starting with the prefix in the template and appending a random string.

Important: If you are using a MySQL database, the usernamePrefix you define should be no more than seven characters long. This keeps usernames generated by Cloudera Director within the MySQL limit of sixteen characters for usernames.

If Cloudera Director creates new external databases during the bootstrap of a deployment or cluster, then it also drops them, and their associated user accounts, when terminating the deployment or cluster. Be sure to back up those databases before beginning termination.

Note: Cloudera Director cannot create databases on remote database servers that Cloudera Director (or code that it runs) is unable to reach. For example, Cloudera Director cannot work with a database server that only allows local access, unless that server happens to be on the same machine as Cloudera Director. Use the following workarounds:

- Reconfigure the database server, and any security measures that apply to it, to allow Cloudera Director access during the bootstrap and termination processes.
- Open an SSH tunnel for database server access.
- Create the databases manually and configure them using normal Cloudera Director support for external databases.

#### API

Define external databases in the templates for new Cloudera Manager installations ("deployments") or new clusters. You cannot define both existing databases, and new databases that need to be created, in the same template.

#### Defining External Databases in the Configuration File

#### **External Databases for Cloudera Manager**

Define external databases used by Cloudera Manager in the cloudera-manager section of a configuration file. The following example defines existing external databases, indicated by the fact that it includes values for the hostnames or IP addresses and the ports.

```
cloudera-manager {
   # ...
   databases {
      CLOUDERA_MANAGER {
        name: scm1
         type: mysql
         host: 1.2.3.4
         port: 3306
         user: scmuser
         password: scmpassword
      ACTIVITYMONITOR {
         name: am1
         type: mysql
         host: 1.2.3.4
         port: 3306
         user: amuser
         password: ampassword
      REPORTSMANAGER {
         name: rm1
         type: mysql
         host: 1.2.3.4
         port: 3306
         user: rmuser
         password: rmpassword
      NAVIGATOR {
         name: nav1
         type: mysql
         host: 1.2.3.4
         port: 3306
         user: navuser
         password: navpassword
      NAVIGATORMETASERVER {
         name: navmetal
         type: mysql
         host: 1.2.3.4
         port: 3306
         user: navmetauser
```

```
password: navmetapassword
   }
}
```

The following example, which does not include hostnames or IP addresses and ports, defines new external databases that Cloudera Director must create while bootstrapping the deployment.

```
cloudera-manager {
   databaseTemplates {
      CLOUDERA_MANAGER {
         name: cmtemplate
         databaseServerName: mysql1
         databaseNamePrefix: scm
         usernamePrefix: cmadmin
      ACTIVITYMONITOR {
         name: cmamtemplate
         databaseServerName: mysql1
         databaseNamePrefix: am
         usernamePrefix: cmamadmin
      REPORTSMANAGER {
         name: cmrmtemplate
         databaseServerName: mysql1
         databaseNamePrefix: rm
         usernamePrefix: cmrmadmin
      NAVIGATOR {
         name: cmnavtemplate
         databaseServerName: mysql1
         databaseNamePrefix: nav
         user: cmnavadmin
      NAVIGATORMETASERVER {
         name: cmnavmetatemplate
         databaseServerName: mysql1
         databaseNamePrefix: navmeta
         usernamePrefix: cmnavmetaadmin
   }
```

Each template must refer to a database server defined elsewhere in the configuration file. The database server template can be for a server that does not yet exist; in that case, Cloudera Director starts creating the server, and then waits while bootstrapping the deployment until the server is available.

A deployment must use either all existing databases or all non-existing databases for the different Cloudera Manager components; they cannot be mixed.

#### For CDH Services

Define external databases used by cluster services such as Hive in the cluster section of a configuration file. The following example defines existing external databases.

```
cluster {
   #...
   databaseTemplates: {
      HIVE {
         name: hivel
         type: mysql
         host: 1.2.3.4
         port: 3306
         user: hiveuser
         password: hivepassword
   }
```

The following example defines new external databases that Cloudera Director must create while bootstrapping the cluster.

```
cluster {
   # . . .
   databaseTemplates: {
      HIVE {
      name: hivetemplate
      databaseServerName: mysql1
      databaseNamePrefix: hivemetastore
      usernamePrefix: hive
}
```

Each template must refer to a database server defined elsewhere in the configuration file. The database server template can be for a server that does not yet exist; in that case, Cloudera Director starts creating the server, and then waits while bootstrapping the cluster until the server is available.

A deployment must use either all existing databases or all non-existing databases for the different cluster services; they cannot be mixed.

# Using EBS Volumes for Cloudera Manager and CDH

Cloudera Director 2.2 and higher supports the use of Amazon Elastic Block Store (EBS) volumes with Cloudera Manager and CDH cluster instances. You can use EBS volumes to store HDFS data, stage data for processing, or install other applications. EBS can provide an efficient and cost-effective alternative to S3 or other storage mechanisms.

Note: An advantage of using EBS volumes for cluster storage is that it allows you to pause your cluster and stop the associated EC2 instances during periods of inactivity. You will still be billed for your EBS volumes while the cluster is paused, but will not be billed for the stopped EC2 instances. For information on pausing a cluster, see Pausing a Cluster in AWS on page 64.

Note: If auto-repair is enabled on a cluster that uses Elastic Block Storage (EBS), you must disable auto-repair for the cluster before stopping either the cluster or the Cloudera Manager instance that manages it. For more information about auto-repair, see Auto-Repair for Failed or Terminated Instances on page 172.

## **EBS Volume Types**

Cloudera Director supports the EBS volume types gp2, st1, and sc1:

EBS volume type	Minimum and Maximum Size	Usage
gp2	1 GiB - 16 TiB	General-purpose SSD (solid state drive) volume that balances price and performance for a wide variety of transactional workloads.
st1	500 GiB - 16 TiB	Low-cost HDD (hard disk drive) volume designed for frequently accessed, throughput-intensive workloads.
sc1	500 GiB - 16 TiB	Lowest-cost HDD (hard disk drive) volume designed for less frequently accessed workloads.

For more information, see Amazon EBS Volume Types.

## Amazon EC2 Instance Stores

Instance stores, like EBS, provide block storage for EC2 instances, but they cannot be used together with EBS volumes. Instance store volumes are located on disks that are physically attached to the host computer, and they are optionally included with many EC2 instance types.

Important: Cloudera Director does not support using instance store volumes together with EBS volumes for the same EC2 instance. All block storage volumes in an instance should be the same size, capacity, and type.

If an instance type has instance store volumes and you do not specify EBS volumes, Cloudera Director automatically mounts all the instance store volumes that are available. If you do specify EBS volumes, Cloudera Director does not mount instance store volumes.

For more information on EC2 instance stores, see Amazon EC2 Instance Stores in the AWS documentation.

## Configuring EBS Volumes

You configure EBS volumes in the instance template in the web UI or in the instance section of the configuration file for clusters launched with the CLI and bootstrap-remote. To configure EBS, provide the following information:

- Number of EBS volumes you want
- Type of the EBS volumes (gp2, st1, or sc1). All EBS volumes for an instance must be of the same type.
- Size of the volumes. Specifying a size outside the ranges defined in the table above causes cluster deployment to
- Encryption
  - Whether or not to encrypt data in the EBS volume
  - Whether to use the default KMS key for the EBS service or use a custom KMS key

EBS volumes for a Cloudera Manager or CDH cluster instance have the same lifecycle as the instance. EBS volumes are terminated when the instance is terminated. Repair of an instance does not result in the remounting of an existing EBS volume; a new volume is used.

## **EBS Volume Encryption**

Data in EBS volumes can be encrypted at rest. You use two properties for configuring EBS encryption:

- enableEbsEncryption: Labeled Enable EBS Encryption in the web UI. Set to true or false. If this value is set to true, the data on EBS volumes created with this instance template will be encrypted.
- ebsKmsKeyId: Labeled EBS KMS Key ID in the web UI. The key used to encrypt data in the EBS volumes. KMS includes a default master key for each service that supports encryption, including EBS. If you leave this field empty, Cloudera Director configures the EBS volumes to use the KMS default master key for EBS. Alternatively, you can import a custom master key from your own key management infrastructure into KMS and specify it here to be used for the EBS service. To specify a custom master key, enter the full Amazon Resource Name (ARN) of the custom master key that you have stored in KMS: arn:aws:kms:your\_key\_name. For example:

arn:aws:kms:us-west-1:635144601417:key/39b8cdf2-923e-721b-9c6c-652a7e517d72

Important: If you specify a custom master key for EBS, you must also add the KMS policy DescribeKey to your IAM policy file so that Cloudera Director can validate the custom master key. For more information and a sample IAM policy file that includes DescribeKey, see Creating AWS Identity and Access Management (IAM) Policies on page 191.

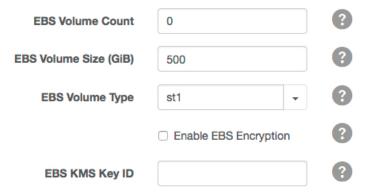

Note: AWS does not support encryption of root volumes. If you have an EBS root volume and you have enabled EBS encryption, the root volume will not be encrypted.

For more information about EBS encryption, see Amazon EBS Encryption in the AWS documentation. For more information about KMS, see AWS Key Management Service Details in the AWS documentation.

#### Configuring an EBS Volume with the Web UI

To configure EBS volumes in the web UI, provide the required values in the Advanced Options section of the instance template:

## Configuring EBS Volumes with the Configuration File

To configure EBS volumes in the configuration file for launching clusters with bootstrap-remote, provide the required values and uncomment them in the EBS Volumes section of the file:

```
EBS Volumes
# Director can create and attach additional EBS volumes to the instance. These volumes
# will be automatically deleted when the associated instance is terminated. These
# properties don't apply to the root volume.
# See http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EBSVolumes.html
# ebsVolumeCount : 0
 ebsVolumeType: st1 # specify either st1, sc1 or gp2 volume type
#
 ebsVolumeSizeGiB: 500
# EBS Volume Encryption
# Encryption can be enabled on the additional EBS volumes. An optional CMK can
 be specified for volume encryption. Not setting a CMK means the default CMK
# for EBS will be used. The encryption here does not apply to the root volume.
# See http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EBSEncryption.html
 enableEbsEncryption: false
 ebsKmsKeyId: arn:aws:kms:REPLACE-ME # full ARN of the KMS CMK
```

## Configuring Device Names for EBS Volumes and Instance Store Volumes

When requesting EC2 instances in Cloudera Director with additional EBS volumes or requesting an instance that contains instance store volumes, Cloudera Director will automatically assign device names to the volumes. For more information about device names in EC2, see Device Naming on Linux Instances in the AWS documentation. The way the device names are assigned to the volumes can be configured. This may be necessary to ensure that the device names used by Cloudera Director doesn't overlap with any additional volumes associated with an AMI.

### Configuring Storage for Cloudera Manager and CDH

By default, instance store volumes will get device names /dev/sdb, /dev/sdc, /dev/sdd, and so on. The device name prefix and starting character can be configured by adding the following section in etc/aws-plugin.conf under the AWS plugin directory.

```
ephemeralDeviceMappings {
    deviceNamePrefix: /dev/sd
    rangeStart: b
}
```

By default, EBS volumes will get device names /dev/sdf, /dev/sdg, /dev/sdh, and so on. The device name prefix and starting character can be configured by adding the following section in etc/aws-plugin.conf under the AWS plugin directory.

```
ebsDeviceMappings
   deviceNamePrefix: /dev/sd
    rangeStart: f
```

Note that Cloudera Director does not attach both instance store volumes and EBS volumes at the same time. If EBS volumes are specified, instance store volumes will not be attached.

# Using Amazon S3 Object Storage

For clusters running on AWS, Amazon S3 (Simple Storage Service) provides an efficient and cost-effective cloud storage option. For information on the uses of Amazon S3 in a CDH cluster, and how to configure Amazon S3 using Cloudera Manager, see How to Configure AWS Credentials and Configuring the Amazon S3 Connector in the Cloudera Enterprise documentation. For links to more topics focused on Amazon S3 from the core Cloudera Enterprise documentation library, see Get Started with Amazon S3.

Note: S3Guard is a feature that guarantees consistent read operations for data stored in Amazon S3. Without S3Guard, Amazon S3 only guarantees "eventual consistency" for data stored in S3, which means that data written to Amazon S3 may not be immediately available for queries and listing operations. S3Guard adds an additional metadata store using an Amazon DynamoDB instance that allows for consistent read operations and improved performance. Instructions for configuring S3Guard in Cloudera Director are included below. For more information on S3Guard, see Configuring and Managing S3Guard in the Cloudera Enterprise documentation.

Important: CDH 5.11.1 clusters using S3Guard can share Amazon DynamoDB tables with CDH 5.12.x clusters, but CDH 5.11.0 clusters cannot share tables with CDH 5.12.x clusters. You must upgrade CDH 5.11.0 clusters using S3Guard to CDH 5.11.1 or higher in order to use the same tables for S3Guard metadata as CDH 5.12 clusters.

### Configuring Amazon S3 with Cloudera Director

Cluster access to Amazon S3 storage can be configured through Cloudera Director by launching your cluster with a configuration file and the bootstrap-remote CLI command. Cloudera Director will make the necessary API calls and pass your AWS access key information or IAM role information to Cloudera Manager so that S3 access is set up according to your configuration settings. Sample content for the sections of the configuration file needed to configure Amazon S3 access is in the aws.reference.conf configuration file, but is commented-out by default. To provide your cluster instances with access to Amazon S3, configure the following sections of the configuration file:

- 1. First, create an external account with AWS access in the External Accounts section of your configuration file. There are two choices for authentication, as described in the configuration file comments, AWS access key authentication or IAM role authentication.
  - To use AWS access key authentication, uncomment the appropriate section shown below and provide an AWS access key and an AWS secret key.

 To use IAM role authentication, uncomment the appropriate section show below and choose or create an IAM policy that includes Amazon S3 access (such as the AWS-managed policy AmazonS3FullAccess) and attach this policy to the IAM role that you assign to your cluster instances. IAM roles for instances that will use S3Guard should also include a policy that gives access to DynamoDB (such as the AWS-managed policy AmazonDynamoDBFullAccess). Specify the IAM role for the instance with the iamProfileName property in the common-instance-properties section of the configuration file.

```
# External accounts
  # # Any external accounts that should be set up within Cloudera Manager. These will
allow some cluster
  # # services to utilize cloud functionality, such as object stores.
  # # Note: CM/CDH 5.10 is required for this feature. At the moment, only AWS external
 accounts are supported.
  # externalAccounts {
        # External account that uses AWS Access Key Authentication. This type of
authentication
        # will also require the AWS_S3 service.
  #
        AWSAccount1
  #
            type: AWS_ACCESS_KEY_AUTH
            configs {
                aws_access_key: REPLACE-ME
  #
                aws_secret_key: REPLACE-ME
  #
  #
              # S3 Guard (added in CM/CDH 5.11) can be enabled to guarantee a consistent
 view of data stored
                # in Amazon S3 by storing additional metadata in a table residing in an
 Amazon DynamoDB instances.
                # See
https://www.cloudera.com/documentation/enterprise/latest/topics/cm_s3quard.html for more
                # details and additional S3 Guard configuration properties.
  #
  #
                # s3quard_enable: false
                # s3guard_region: REPLACE-ME
  #
                # s3guard_table_name: s3guard-metadata
  #
                # s3guard_table_auto_create: false
            }
  #
  #
  #
        # External account that uses IAM Role Authentication.
  #
        AWSAccount2 {
            type: AWS_IAM_ROLES_AUTH
  #
```

Optionally, to use S3Guard with IAM role authentication, copy the S3Guard configurations from the access key authentication configs block to the IAM role authentication section and configure them.

```
# s3guard_enable: false
  # s3guard_region: REPLACE-ME
  # s3guard_table_name: s3guard-metadata
  # s3guard_table_auto_create: false
```

For descriptions of the S3Guard configuration properties, see the table in Configuring S3Guard in the Enterprise documentation. Use the API names given in this table when adding properties to the configs block of the Cloudera Director configuration file. For more information about the differences between AWS access key authentication and IAM role-based authentication, and the characteristics and use cases for each of them, see the sections on each in How to Configure AWS Credentials in the Enterprise documentation.

**Note:** When you bootstrap a cluster with Cloudera Director that is configured to use external accounts, you will see the external accounts in the Cloudera Director web UI. But if you use Cloudera Manager to add external accounts to an existing cluster, while these external accounts will be functional and available to use, they will not appear in the Cloudera Director web UI. In this case, you must use Cloudera Manager to view all external accounts for the cluster.

2. Next, if you are using access key authentication, add (or uncomment) the Cloudera S3 Connector service, AWS\_S3, in the list of cluster services in the Cluster description section of the configuration file. You should also add the AWS\_S3 service with IAM role-based authentication if you are enabling S3Guard. Use of IAM role authentication doesn't require adding the AWS\_S3 service if S3Guard is not enabled.

```
services: [
               HDFS,
                YARN.
                ZOOKEEPER,
               HBASE.
               HIVE,
               HUE,
               OOZIE,
               SPARK_ON_YARN,
               KAFKA,
               SOLR,
               FLUME,
                IMPALA,
               SQOOP,
               ACCUMULO16,
               KS_INDEXER,
                # SENTRY,
                             # Sentry requires Kerberos to be enabled
               SPARK2_ON_YARN,
               KUDU,
               # AWS_S3
                             # Requires Sentry and Kerberos (on default configurations)
```

**3.** Finally, point the AWS\_S3 service to the external account you created in step #1 above in the **custom service configurations** section :

```
#
    # Optional custom service configurations
    # Configuration keys containing special characters (e.g., '.', ':') must be enclosed
 in double quotes.
    # Configuration properties for CDH roles and services are documented at
https://www.cloudera.com/documentation/enterprise/properties/5-11-x/topics/cm props_cdh5110.html
    #
      configs {
          AWS_S3 {
    #
            cloud_account: AWSAccount1
    #
    #
          HDFS {
    #
    #
            dfs_block_size: 134217728
    #
    #
    #
          MAPREDUCE {
    #
            mapred_system_dir: /user/home
    #
            mr_user_to_impersonate: mapred1
    #
    #
    #
          KAFKA {
             "num.partitions": 3
    #
    #
    # }
```

Note: By default, as noted in the comment in the configuration file shown in step 2 above, Sentry and Kerberos are required for the AWS\_S3 service. You can disable this requirement by setting the key\_distribution\_policy to UNSECURE in the configs section of the configuration file (shown in step 3 above).

```
AWS_S3 {
 cloud_account: AWSAccount1
 key_distribution_policy: UNSECURE
```

## Shrinking an H2 Database

Note: You should not use H2 for production clusters. Cloudera strongly recommends using MySQL or MariaDB for production deployments instead of H2. Use of the H2 database in production environments can result in excessive space consumption for database files and slow database access. Also, unlike managed MySQL and MariaDB databases, H2 files are not backed up regularly, which puts your production deployment of Cloudera Director at risk of data loss. For instructions on migrating from H2 to MySQL or MariaDB, see the following topics:

- Using MySQL for Cloudera Director Server on page 115
- <u>Using MariaDB for Cloudera Director Server</u> on page 128

If you use an H2 database for Cloudera Director's data, the database should not be larger than a few megabytes. The H2 database grows when Cloudera Director runs over a long period of time because the database is not able to reclaim disk space when entries are deleted. As the database file grows larger, the risk of database corruption increases.

You can reduce the size of the H2 database by exporting and importing all the data using H2's Script and RunScript commands.

- 1. Back up the existing H2 database file.
- **2.** Stop Cloudera Director.
- **3.** Make a backup script using H2's **Script** command:

```
# Make a backup script (backup.zip)
# NOTE: Do not include '.h2.db' when specifying the db file
$ java -cp <h2 jar file> org.h2.tools.Script -url \
  "jdbc:h2:/var/lib/cloudera-director-server/state;MV_STORE=false; \
MVCC=true;DB_CLOSE_ON_EXIT=TRUE;AUTO_SERVER=TRUE;TRACE_LEVEL_FILE=4;TRACE_LEVEL_SYSTEM_OUT=0"
  -user sa -password sa -script backup.zip -options compression zip
```

Note: Both code snippets in these instructions include the default location for the H2 database file, /var/lib/cloudera-director-server/state.h2.db. Edit this part of the code snippets if your database file is in a non-default location.

Important: In both code snippets, omit . h2.db in the path to the database file. Otherwise H2 will look for a state.h2.db.h2.db file and create it if it doesn't exist.

4. Delete the old database.

## Configuring Storage for Cloudera Manager and CDH

**5.** Create a new, smaller database from the script using H2's **RunScript** command:

```
# Create a new database from the script (backup.zip)
# NOTE: Do not include `.h2.db' when specifying the db file
$ java -cp <h2 jar file> org.h2.tools.RunScript -url \
    "jdbc:h2:/var/lib/cloudera-director-server/state;MV_STORE=false; \
MVCC=true;DB_CLOSE_ON_EXIT=TRUE;AUTO_SERVER=TRUE;TRACE_LEVEL_FILE=4;TRACE_LEVEL_SYSTEM_OUT=0"
    -user sa -password sa -script backup.zip -options compression zip
```

#### 6. Start Cloudera Director.

For more information on H2 databases, see the H2 documentation at H2 Database Engine.

# Security, Encryption, and High Availability

This section explains how to use security, encryption, and high availability features supported in Cloudera Director.

# Enabling TLS with Cloudera Director

Transport Layer Security (TLS) is a security protocol that supersedes Secure Sockets Layer (SSL). It is designed to prevent eavesdropping, tampering, and message forgery by encrypting network communications. It also supports authentication of host certificates prior to encryption, to prevent spoofing. You can enable TLS on your clusters, as well as on Cloudera Manager and Cloudera Director, in order to protect communications among them.

**Note:** This document assumes you are familiar with TLS and SSL concepts like public and private keys, public key certificates, and certificate authorities. Cloudera recommends that you also be familiar with enabling TLS for Cloudera Manager and CDH. For more information, see Configuring Cloudera Manager Clusters for TLS/SSL and Configuring TLS/SSL Encryption for CDH Services. For a list of documentation topics on using TLS with Cloudera Manager and CDH, search for TLS using the Categories feature at the bottom of any page of the Cloudera Manager or CDH documentation, or click here.

## Automatic TLS (Auto-TLS)

Cloudera Director can work in concert with Cloudera Manager 5.13 or later to automatically configure TLS for Cloudera Manager and CDH. This is called auto-TLS. Auto-TLS replaces the work otherwise performed manually to create key pairs and public key certificates, copy them into the correct locations for Cloudera Manager and CDH, and alter Cloudera Manager and CDH component configurations to use them and support access over TLS. Auto-TLS configures TLS as soon as possible, often before relevant services are started, so there is no span of time when services are listening for unencrypted traffic.

Auto-TLS creates a bespoke certificate authority (CA) on the Cloudera Manager server instance. All certificates generated by auto-TLS are signed by this CA. Since the CA does not exist before Cloudera Manager is installed, and because the root certificate for the CA is not itself signed by a pre-existing CA, it is difficult to establish trust for the certificates ahead of time. If you wish to have certificates signed by a pre-existing CA instead of the bespoke CA, then continue to set up TLS manually, and follow the instructions in Manual TLS to configure Cloudera Director to communicate with Cloudera Manager over TLS.

#### **Using Auto-TLS**

To use auto-TLS, you must either use a Cloudera Director configuration file or Cloudera Director's REST API for bootstrapping Cloudera Manager. Auto-TLS is not available through the Cloudera Director UI.

Warning: In Cloudera Director 2.6, when a custom DNS is used with auto-TLS, host name selection can fail. Cloudera recommends that users of auto-TLS use Cloudera Director 2.7.0 or higher, where this issue has been fixed. See the <u>Cloudera Director 2.7 release notes</u> for more information.

To enable auto-TLS for a Cloudera Manager deployment using a configuration file, simply include the tlsEnabled property in the cloudera-manager section, set to true.

```
cloudera-manager {
    tlsEnabled: true
```

### Security, Encryption, and High Availability

To enable auto-TLS for a Cloudera Manager deployment using the Cloudera Director REST API, simply set the tlsEnabled property of the deployment template to true. You must use at least version 10 of the API. An example JSON snippet is below.

```
"tlsEnabled": true,
```

When auto-TLS is enabled for a Cloudera Manager deployment, every CDH cluster managed by that Cloudera Manager installation is also automatically configured for TLS. If it is necessary for a CDH cluster to not be configured for TLS while Cloudera Manager is, then follow the instructions for Manual TLS to configure Cloudera Manager instead.

Use of auto-TLS causes the automatic installation of unlimited strength JCE policy files on the Cloudera Manager instance by Cloudera Director. The policy files eliminate runtime restrictions on the strength of cryptographic algorithms that are included in Java.

Important: If you are in a legal jurisdiction where use of unlimited strength JCE policy files is prohibited, then do not use auto-TLS. Instead, follow the instructions for Manual TLS.

Cloudera Director automatically retrieves the root certificate of the bespoke CA used in auto-TLS from the Cloudera Manager instance, and establishes trust in it. This creates an opportunity for a man-in-the-middle attack on the SSH connection Cloudera Director uses for the retrieval. For protection against such an attack, consider configuring SSH host key retrieval and verification.

## Retrieving the CA Root Certificate

When a browser or other web client accesses a Cloudera Manager instance set up under auto-TLS, the browser or web client should emit a warning that the server certificate for Cloudera Manager is not trusted. This is because the certificate is signed by the bespoke CA resident on the Cloudera Manager instance, and that CA is not trusted by any of the well-known default CAs installed in the client. It is possible to override or ignore these warnings, but a more secure option is to import the root certificate of the CA into the client.

There are a few ways to retrieve the root certificate of the bespoke CA, so that it can be imported into the trusted certificate store of a client. One easy way is to use the Cloudera Director REST API, or an API client library, to get the deployment corresponding to the Cloudera Manager instance. The result data includes the root certificate as the trustedCertificate field. The value of the field is a single line containing the entire certificate contents; to use the 

http://director\_host:7189/api/v10/environments/env\_name/deployments/dep\_name

```
"name": "dep_name",
  "hostname": "203.0.113.101",
  "port": 7183,
  "tlsEnabled": true,
  "trustedCertificate": "----BEGIN CERTIFICATE----\r\nMII...\r\n----END
CERTIFICATE----\r\n",
```

Once the root certificate is imported for a client, it should be trusted, and no connection warnings should appear.

#### Advanced Auto-TLS Configuration

Auto-TLS requires no detailed configuration in order to work properly. However, there are a set of TLS configuration properties that may be passed through a Cloudera Director deployment template to Cloudera Manager. The properties are listed below; each property's key and value is a string.

**Table 5: TLS Configuration Properties** 

Property Name	Purpose	Default Value
trusted_ca_certs	path to a file containing a concatenation of certificates to be trusted by cluster services	none; see below
subject_suffix	suffix for DNs generated for auto-TLS	"ST=CA,C=US"
ca_dn	complete DN for CA root certificate (overrides ca_name and subject_suffix)	none
ca_name	CN for subject DN of CA root certificate, used in concert with subject_suffix; may not exceed 64 characters	"SCM Local CA on deployment deployment-name", truncated if necessary to 64 characters
email_address	email address to include as subject alternative name (SAN) on all certificates	none
ca_key_algo	algorithm used to generate CA key: RSA, DSA, or EC	RSA
ca_key_args	arguments for CA key generation: for RSA and DSA, key length; for EC, curve name	3072
ca_sig_hash_algo	hash algorithm for CA key signature: SHA256, SHA512	SHA256
host_key_algo	algorithm used to generate host keys: RSA, DSA, or EC	RSA
host_key_args	arguments for host key generation: for RSA and DSA, key length; for EC, curve name	3072
host_sig_hash_algo	hash algorithm for host key signatures: SHA256, SHA512	SHA256
ca_expiration	date of CA certificate expiration, in YYMMDD format	about one year from current time
host_expiration	date of host certificate expirations, in YYMMDD format	about one year from current time
key_encryption_algo	encryption used for private keys stored on Cloudera Manager instance: AES128, or AES256	AES256
keytool	path to Java keytool on Cloudera Manager instance	see below

The trusted\_ca\_certs TLS configuration property is useful when cluster services need to connect over TLS to external endpoints, and the server certificates for those endpoints are not ultimately signed by widely acknowledged CAs. The self-signed server or CA certificates for those endpoints, in PEM format, should be included in the file indicated by the property. Since the property value is a path to a file containing the certificates, and not the certificates themselves, measures must be taken to ensure that the file is in place at the indicated path on the Cloudera Manager instance; for example, the file could be included in the instance's base image, or the file could be written through a bootstrap script.

### Security, Encryption, and High Availability

The host\_expiration and ca\_expiration TLS configuration properties set the expiration dates for server certificates issued for cluster services and for the Cloudera Manager server, respectively. They default to a date about one year in the future from the time when the certificates are issued. Beyond the expiration dates, the certificates are not accepted by TLS clients. Auto-TLS does not support the renewal of automatically generated certificates, so for long-lived clusters, specify expiration dates further in the future.

If the keytool TLS configuration property is passed to Cloudera Director, then its value is used as is. Otherwise, Cloudera Director attempts to locate keytool on the running Cloudera Manager instance. If Cloudera Director succeeds in locating keytool, it passes the path to keytool to Cloudera Manager; otherwise, it passes a default of keytool, which works if keytool is on the default PATH.

To set a TLS configuration property using a configuration file, include its key and desired value in a simple object named tlsConfigurationProperties in the cloudera-manager section. If no TLS configuration properties need to be set, the tlsConfigurationProperties object may be omitted.

```
cloudera-manager {
    tlsEnabled: true
    tlsConfigurationProperties {
         ca_key_args: 4096
        host_key_args: 4096
; · ·
```

To set a TLS configuration property using the Cloudera Director REST API, include it in the tlsConfigurationProperties map property of the deployment template. An example JSON snippet is below. If no TLS configuration properties need to be set, the tlsConfigurationProperties map property may be omitted or left empty.

```
"tlsEnabled": true,
"tlsConfigurationProperties": {
  "ca_key_args": "4096",
  "host_key_args": "4096"
},
```

Cloudera Director does not attempt to validate TLS configuration properties, so any unknown or invalid properties are passed through as-is to Cloudera Manager. Check Cloudera Director and Cloudera Manager logs if the configuration properties appear to cause problems or have no effect.

#### Name Length Restrictions

Some standard naming restrictions are relevant when configuring TLS.

- The fully-qualified domain name (FQDN) of a Linux instance may be up to 255 characters in length.
- The value of the common name (CN) attribute in a distinguished name (DN) may not exceed 64 characters.

Because auto-TLS normally uses the FQDN of an instance as the value of the CN attribute in that instance's certificate's subject DN, it is possible for certificate generation to fail if that FQDN is too long. When the FQDN exceeds 64 characters, a certificate with the FQDN as the value for the CN attribute cannot be generated.

This is of particular importance when using Google Compute Engine, which includes an instance's Cloudera Director virtual instance ID, a 36-character UUID, in the instance's hostname. Google Compute Engine also uses the project name as part of the domain name, consuming more characters from the allowed total of 64.

Therefore, when using auto-TLS, you may need to specify a short instance name prefix for Cloudera Director instance templates in order to stay below the 64-character limit. In the Cloudera Director UI, the instance name prefix is specified under the Advanced Options when creating or editing an instance template. In a Cloudera Director configuration file,

the instance name prefix may be specified in the "provider" section when using either AWS, Google Cloud Platform, or Microsoft Azure as a cloud provider.

```
provider {
  instanceNamePrefix: abc
```

#### Static Private IP Addresses

In order to be compatible with Cloudera Director, the server certificate for the Cloudera Manager instance must include its private IP address as a subject alternative name (SAN). If the instance changes its private IP address, perhaps by being stopped and started again, then Cloudera Director will not be able to communicate with Cloudera Manager over TLS due to the mismatch.

There is currently no mechanism in auto-TLS to accommodate a change in the private IP address of the Cloudera Manager instance. Therefore, it is essential that the private IP address for the Cloudera Manager instance be assigned until the instance is terminated, and not released when it is stopped.

This is the normal behavior for instances under AWS and Google Cloud Platform. However, the default behavior for Microsoft Azure is to use *dynamic* private IP address allocation, which can cause the private IP address to change when the VM is stopped and then started again. In constrast, a static private IP address allocation remains with a VM until it is terminated. To change the private IP address allocation for an Azure VM from dynamic to static, use the Azure portal or Powershell. For more information about configuring Cloudera Director on Azure to use static IP addresses, see the first note in Notes on Pausing a Cluster on the page Pausing Cloudera Director Instances.

#### Coping with Untrusted Certificates Created by Auto-TLS

Server certificates signed by the bespoke CA are not trusted by web browsers or other clients, leading them to either produce warnings or refuse to complete TLS handshakes. There are several strategies for coping with the certificates.

First, clients can be configured to trust the root certificate of the CA by importing that certificate into the client's trusted certificate store. Once this is done, the client trusts any server certificates signed by the CA, just as it would for those signed by widely recognized CAs. However, this process must be performed for each new CA that is created by auto-TLS, and it usually requires manual steps.

A more user-friendly solution is to place a reverse proxy in front of Cloudera Manager and the cluster services. A reverse proxy can be configured to listen over TLS, using a server certificate signed by a recognized CA so that clients need not import any new trusted certificates. The server name for the proxy may be in your organization's domain and managed by your organization's CA, whether internal or third-party. In response to requests, the reverse proxy then can route new requests, again over TLS, to Cloudera Manager and cluster services.

For example, here is a configuration snippet for the nginx HTTP server and proxy that routes incoming TLS requests to the HDFS namenode web UI, also serving over TLS. In the example, hadoopproxy is the hostname of the instance hosting nginx, and nn.cloudprovider.internal refers to the instance hosting the HDFS namenode. A client request to https://hadoopproxy/connects to the HDFS namenode web UI, even if the client cannot reach the HDFS namenode instance directly.

```
server {
  listen 443 ssl;
  server_name hadoopproxy;
  # public key certificate for nginx, signed by recognized CA
  ssl_certificate /etc/nginx/cert.pem;
  # private key for nginx
  ssl_certificate_key /etc/nginx/key.pem;
  location /
    proxy_pass https://nn.cloudprovider.internal:50470/;
    # root certificate for bespoke CA on Cloudera Manager instance
    proxy_ssl_trusted_certificate /etc/nginx/cmca.crt;
    proxy_ssl_verify on;
    proxy_ssl_verify_depth 2;
```

```
proxy_ssl_session_reuse on;
}
```

Cloud provider load balancing services can also work as reverse proxies. For example, an application load balancer created through AWS Elastic Load Balancing (ELB) may be configured as a reverse proxy, listening for requests over TLS using a server certificate signed by a recognized CA and forwarding them over TLS to Cloudera Manager or cluster service web UIs. Check the documentation for your cloud provider for the available options.

#### Manual TLS

You may wish to set up TLS manually for Cloudera Manager and CDH instead of through the auto-TLS capability. One common reason for doing so is in order to use certificates signed by an existing CA, as opposed to the bespoke CA set up under auto-TLS. Cloudera Director supports this workflow by allowing you to enable TLS, via the Cloudera Director API, on a bootstrapped deployment.

The process of configuring TLS manually for Cloudera Manager and CDH is documented in Configuring Cloudera Manager Clusters for TLS/SSL, and the same process should be followed for installations bootstrapped by Cloudera Director. After the initial part of the process, Level 0, Cloudera Director must be updated to use TLS for communication. The remaining parts of the process should still be performed.

#### Configuring Level 0 for Cloudera Manager

Start by bootstrapping a deployment and cluster normally, without TLS enabled. Once the deployment and cluster are READY in Cloudera Director, perform the usual manual steps for configuring TLS in Cloudera Manager, with a slight modification explained below. See Level 0: Basic TLS/SSL Configuration for more information. The only steps that must be performed before updating Cloudera Director are those for Level 0, which reconfigure the Cloudera Manager server to use TLS. For complete Cloudera Manager TLS configuration, after updating Cloudera Director, be sure to continue the steps after Level 0 as usual for securing Cloudera Manager and CDH manually.

In order to be compatible with Cloudera Director, the server certificate for Cloudera Manager must include a subject alternative name (SAN) with the private IP address of the Cloudera Manager instance. The stock instructions for configuring Level 0 do not include a SAN, but keytool allows specifying one using the `-ext` option. The example below illustrates how to use the '-ext' option with an IP address and a hostname; replace the sample IP address with the correct one when used. Because TLS clients may ignore the hostname in the common name (CN) attribute of the certificate's subject DN in lieu of SANs, you should include the hostname as a SAN as well.

```
$ sudo keytool -genkeypair -alias $(hostname -f)-server -keyalg RSA \
 -keystore /opt/cloudera/security/pki/$(hostname -f)-server.jks \
-keysize 4096 -dname "CN=$(hostname -f),O=cloudera.com,ST=CA,C=US"
 -ext "san=ip:203.0.113.101,dns:$(hostname -f)" \
 -storepass cloudera -keypass cloudera
```

During Level 0 configuration, you have the opportunity to have the public key certificate for the server signed by a CA. If desired, you may proceed with a self-signed certificate. To generate a self-signed certificate from the server key pair, use keytool. The self-signed certificate must be imported into the Java truststore (the file issecacerts created in the Level 0 documentation), just as the root certificate for an internal CA would need to be. Be sure to perform this extra step after generating a self-signed certificate, instead of generating a certificate signing request (CSR).

```
$ sudo keytool -exportcert -rfc \
 -keystore /opt/cloudera/security/pki/$(hostname -f)-server.jks \
 -alias $(hostname -f)-server \
 -file /opt/cloudera/security/pki/$(hostname -f)-server.crt \setminus
 -storepass cloudera -keypass cloudera
```

A self-signed certificate is untrusted by browser and other web clients, so there is often no reason to use one instead of taking advantage of auto-TLS.

#### **Updating Cloudera Director**

Any time after Level 0 configuration is complete, it is possible to update the deployment information in Cloudera Director to enable TLS communication. Two pieces of information are required:

- 1. The encrypted port number for Cloudera Manager. This is usually 7183.
- 2. Either the self-signed certificate for the Cloudera Manager server or, if using an internal CA, either the signed public key certificate for the server or the root certificate for the internal CA. No matter which certificate you choose, it is called the trusted certificate for the deployment.

Retrieve the deployment template for Cloudera Manager from Cloudera Director's REST API. You must use version 10 or higher of the Cloudera Director API. API access is available through the API console at

http://director\_host:7189/api-console/, or through a Cloudera Director API client library, or directly using your preferred REST client framework.

http://director\_host:7189/api/v10/environments/env\_name/deployments/dep\_name/template

Edit the returned JSON to add or change the following fields in the top-level object:

- tlsEnabled, with a value of true
- port, with the port number as its numeric value, even if the default port of 7183 is to be used
- trustedCertificate, with a string value matching the contents of the trusted certificate; because the certificate is multiple lines, replace each newline in it with a two-character n string

Here is an example of the new fields, with most of the contents of the trusted certificate omitted for brevity:

```
"tlsEnabled": true,
"port": 7183,
"trustedCertificate": "----BEGIN CERTIFICATE----\nMII...\n----END CERTIFICATE--
```

Finally, update the deployment by issuing an HTTP PUT to the deployment update endpoint. Include the entire modified deployment template in the request body, not just the new fields.

http://director\_host:7189/api/v10/environments/env\_name/deployments/dep\_name

During the deployment update process, Cloudera Director attempts to connect to Cloudera Manager over TLS, using the port and trusted certificate supplied in the update. The update will fail if Cloudera Director cannot successfully connect.

#### Completing Manual TLS

After successful deployment update, Cloudera Director will communicate with Cloudera Manager exclusively over TLS. Be sure to return to the documented process of configuring TLS for other components of Cloudera Manager, such as its agents, to complete the work of securing Cloudera Manager and CDH clusters.

## **Disabling Manual TLS**

If it becomes necessary to disable TLS for Cloudera Manager, it is possible to update Cloudera Director so that it communicates over unencrypted HTTP to Cloudera Manager. Performing such an update is only necessary if TLS is disabled for the Cloudera Manager API and web interface; if TLS is only disabled, say, for Cloudera Manager agent communication, then Cloudera Director does not need to be updated. In other words, Cloudera Director should be updated only if Level 0 is unconfigured for Cloudera Manager.

Also, if TLS is disabled only temporarily for Cloudera Manager, and then re-enabled soon afterward, then Cloudera Director will re-establish communication on its own. While TLS is disabled for Cloudera Manager, Cloudera Director will be unable to communicate with it. Often this is not a problem. However, health reports, refresh processes, and usage-based billing will not function while Cloudera Director is out of contact.

Disabling TLS for Cloudera Manager should not be necessary when auto-TLS is in use. These instructions assume that TLS was configured manually for Cloudera Manager.

Begin by retrieving the deployment template for Cloudera Manager from Cloudera Director's REST API. You must use version 10 or higher of the Cloudera Director API. API access is available through the API console at

### Security, Encryption, and High Availability

http://director\_host:7189/api-console/, or through a Cloudera Director API client library, or directly using your preferred REST client framework.

http://director\_host:7189/api/v10/environments/env\_name/deployments/dep\_name/template

Edit the returned JSON to add or change the following fields in the top-level object:

- tlsEnabled, with a value of false
- port, with the port number as its numeric value, even if the default port of 7180 is to be used
- trustedCertificate, which should be omitted completely from the template

Here is an example of the updated fields:

```
"tlsEnabled": false,
"port":7180
```

Finally, update the deployment by issuing an HTTP PUT to the deployment update endpoint. Include the entire modified deployment template in the request body, not just the updated fields.

http://director\_host:7189/api/v10/environments/env\_name/deployments/dep\_name

During the deployment update process, Cloudera Director attempts to connect to Cloudera Manager over an unencrypted connection, using the port supplied in the update. The update will fail if Cloudera Director cannot successfully connect.

After successful deployment update, Cloudera Director will communicate with Cloudera Manager without TLS. If or when TLS is enabled once again for Cloudera Manager, repeat the procedure above for updating Cloudera Director to communicate over TLS.

## Working with an Existing Cloudera Manager

Cloudera Director allows you to bootstrap a cluster using a deployment of Cloudera Manager that already exists, and was not itself created by Cloudera Director. When using an existing Cloudera Manager, auto-TLS is not available. However, Cloudera Director can still work with an existing Cloudera Manager installation over TLS.

If the existing Cloudera Manager installation is already configured for TLS, then the Cloudera Director configuration file should indicate that in the cloudera-manager section by:

- setting the tlsEnabled property to true
- optionally setting the port property to the encrypted port (or else the default of 7183 is used)
- setting the trustedCertificate property to a string value matching the contents of the trusted certificate; because the certificate is multiple lines, replace each newline in it with a two-character \n string

If the existing Cloudera Manager installation is not configured for TLS when the cluster is bootstrapped, but TLS is then manually enabled later, then you should update the deployment information in Cloudera Director. See <u>Updating Cloudera Director</u> above for instructions on how to do so; the procedure is identical to that for a Cloudera Manager installation that was originally bootstrapped by Cloudera Director. As noted above, the server certificate for Cloudera Manager must include a *subject alternative name* (SAN) with the private IP address of the Cloudera Manager instance in order to be compatible with Cloudera Director.

#### TLS for Cloudera Director Itself

Cloudera Director itself may be configured for TLS. When this is done, the Cloudera Director server, including its API endpoints, require TLS for access. Configuring Cloudera Director itself for TLS is an independent activity from configuring Cloudera Manager and CDH clusters for TLS, although a comprehensive security plan may mandate them both. Cloudera Director may be configured for TLS either before or after any Cloudera Manager deployments.

#### **Configuring Cloudera Director for TLS**

Cloudera Director is configured for TLS by setting its own configuration properties in its application.properties file. See <a href="Setting Cloudera Director Properties">Setting Cloudera Director Properties</a> for information on where the file is located and details on how to set properties.

Property	Description
server.ssl.key-store	Path to keystore holding server's private key and public key certificate.
server.ssl.key-store-password	Password for keystore.
server.ssl.key-store-type	Type of keystore. Optional.
server.ssl.key-store-alias	Alias of private key in keystore, for JKS type keystores. The default is to expect only a single alias in the keystore. Optional.
server.ssl.key-password	Password for private key, if different from password for keystore. Optional.

Additional properties are supported. Consult the Spring Boot documentation on configuring SSL for details.

After setting TLS configuration properties, restart Cloudera Director for it to begin requiring TLS. Director continues to listen on the same port as before (default 7189) unless configured for a different port.

Once Cloudera Director is configured for TLS, access its web interface using https URLs. If the server certificate is not signed by a certificate authority recognized by the client (for example, the web browser), then take the appropriate steps to either add an exception for the server or add the server certificate, or one from a responsible certificate authority, to the client's truststore.

#### Generating a Test Keystore for Cloudera Director

To generate a simple test keystore for Cloudera Director, use the keytool command. An example command is below.

```
$ keytool -genkeypair -alias director -keyalg RSA \
  -keystore director.jks \
  -keysize 4096 -dname "CN=$(hostname -f),O=cloudera.com,ST=CA,C=US" \
  -storepass cloudera -keypass cloudera
```

Use a valid hostname for the CN (common name) component of the subject DN (distinguished name) for the public key certificate. Doing so allows clients to perform hostname verification.

Then, configure Cloudera Director with this keystore to enable TLS. Note that since the public key certificate in the keystore is self-signed, clients such as web browsers will issue warnings that the certificate is not trusted.

```
server.ssl.key-store: /path/to/director.jks
server.ssl.key-store-password: cloudera
```

To extract the self-signed certificate from the test keystore, use keytool again, as in the following command. The resulting certificate file can be imported into a truststore using the keytool -importcert command.

```
$ keytool -exportcert -rfc \
  -keystore director.jks -alias director \
  -file director.crt -storepass cloudera -keypass cloudera
```

Avoid using a self-signed certificate for Cloudera Director in a production environment. Instead, use a certificate signed by a recognized certificate authority.

#### Using the Cloudera Director Client under TLS

When the Cloudera Director server is configured for TLS, remote commands issued to the Cloudera Director client, such as bootstrap-remote and terminate-remote, must indicate that TLS is enabled on the server. Do so by passing the following configuration properties to the client:

- lp.remote.tlsEnabled, set to true
- lp.remote.hostAndPort, set to the hostname used in the CN component of the subject DN of the server certificate, followed by a colon and the server port

Here is an example bootstrap-remote command that works with a Cloudera Director server that has TLS enabled.

```
$ cloudera-director bootstrap-remote myconfig.conf \
  --lp.remote.hostAndPort=$(hostname -f):7189 \
  --lp.remote.username=admin --lp.remote.password=admin \
  --lp.remote.tlsEnabled=true
```

#### **Trusting the Cloudera Director Server Certificate**

The Cloudera Director client relies on the default Java truststore to locate trusted certificates. If the server is using a server certificate that is not signed by a certificate authority whose root certificate is in the truststore, then the client will not be able to connect to the server.

To add a server certificate or certificate authority root certificate to a Java truststore, use a keytool command such as the one below, which assumes that the certificate is being added to a copy of the standard cacerts truststore file.

```
$ cp $JAVA_HOME/jre/lib/security/cacerts directorclientts.jks
$ keytool -importcert -alias director -file director.crt \
  -keystore directorclientts.jks -storepass changeit -noprompt
```

To use a custom truststore with the Cloudera Director client, set the appropriate Java SSL system properties using the DIRECTOR CLIENT JAVA OPTS environment variable. At least the "javax.net.ssl.trustStore" property must be set. The contents of the environment variable are passed to the Cloudera Director client JVM when using the cloudera-director run script.

```
$ export DIRECTOR_CLIENT_JAVA_OPTS=\
"-Djavax.net.ssl.trustStore=/path/to/directorclientts.jks \
-Djavax.net.ssl.trustStorePassword=changeit"
$ cloudera-director bootstrap-remote ...
```

#### **Disabling Hostname Verification**

Note: Disabling hostname verification introduces additional risk when using TLS, and should therefore not be used unless necessary. Proceed at your own risk.

By default, the Cloudera Director client performs normal hostname verification based on the CN component of the subject DN. Hostname verification may be disabled by passing the lp.remote.hostnameVerificationEnabled configuration property to the client, set to false (the property's default value is true).

This is helpful, for example, when connecting to a Cloudera Director instance whose certificate specifies a hostname that is private to your cloud provider, but a different, public hostname must be used. (A superior resolution to this problem is to include the public hostname as a subject alternative name in Cloudera Director's server certificate.)

```
$ cloudera-director bootstrap-remote myconfig.conf \
  --lp.remote.hostAndPort=public-hostname.company.com:7189 \
  --lp.remote.username=admin --lp.remote.password=admin \
  --lp.remote.tlsEnabled=true \
  --lp.remote.hostnameVerificationEnabled=false
```

## TLS for Cloudera Director's Database

By default, when the Cloudera Director server is configured to use a MySQL or Maria DB database for its own data, it communicates with the hosting MySQL or Maria DB server over an unencrypted connection. You can configure the Cloudera Director server to communicate with the MySQL or Maria DB server over TLS.

Note: This section is about the data Cloudera Director server stores for its own use, and not for databases used by Cloudera Manager or cluster services.

Note: For information on configuring Cloudera Director to use a MySQL database, see Using MySQL for Cloudera Director Server. For information on configuring Cloudera Director to use a MariaDB database, see Using MariaDB for Cloudera Director Server.

Setting up TLS for communication with MySQL or Maria DB adds a few steps to the general procedures described in Using MySQL for Cloudera Director Server and Using MariaDB for Cloudera Director Server. As part of configuring the MySQL server, include the configuration options needed for TLS support. Consult MySQL documentation for complete information, depending on the version of MySQL in use. Some example options:

```
[mysqld]
ssl-ca=ca.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

## In this example:

- ca.pem is a file containing the certificate for the certificate authority (CA) that has signed the server certificate
- server-cert.pem is a file containing the public key certificate for the server
- server-key.pem is a file containing the private key for the server

Configure the set of lp.database configuration properties for the Cloudera Director server as usual to point to the MySQL or Maria DB database server and the Cloudera Director database created within it. Be sure to explicitly supply values for lp.database.host, lp.database.port, and lp.database.name, even if their defaults apply.

Then, set the value of the lp.database.url configuration property to the following (all on one line):

```
jdb::mysql://${lp.database.host}:${lp.database.port}/${lp.database.name}?verifyServerOertificate=trueEccentrations
```

Finally, import the CA certificate to the Java system truststore. This allows Cloudera Director to trust the server certificate used by the MySQL server. Use a unique, appropriate alias for the certificate in the truststore. Do this before starting Cloudera Director.

```
sudo keytool -importcert -keystore $JAVA_HOME/lib/security/cacerts \
 -file ca.pem -alias mysqlca
```

As an alternative to importing the certificate into the Java system truststore, you may import the certificate into a separate truststore that is passed to Cloudera Director via the <code>javax.net.ssl.trustStore</code> system property. If you do this, be sure the separate truststore contains all other necessary certificates for Cloudera Director to function, such as those providing the basis of trust for communicating with your chosen cloud provider, and either Cloudera Director's own server certificate or a CA certificate in its chain.

When the Cloudera Director server is started, it will communicate with the MySQL or Maria DB server over TLS. If TLS communications cannot be established, Cloudera Director will exit.

Cloudera Director may fail to start and report the error "Path does not chain with any of the trust anchors" in its log. This may occur depending on the version of Java in use and characteristics of the CA root certificate. If this error appears, then import the server certificate for the MySQL or Maria DB server itself into the truststore and restart the Cloudera Director server.

#### Using an AWS RDS MySQL Server

You may use a MySQL server launched from AWS RDS to host Cloudera Director's database. RDS automatically configures each MySQL database instance to support TLS connections, generating an appropriate server certificate for the instance during launch time. The server certificate is signed by a CA maintained by RDS itself.

You must import a certificate from RDS into the Java truststore for Cloudera Director to be able to communicate with the RDS instance over TLS. RDS maintains a root CA that governs most of its regions. RDS also maintains intermediate CAs for each region. Either the root CA certificate or the intermediate CA certificate for the region where the MySQL server resides should work to establish trust from Cloudera Director to the RDS instance over TLS.

Download the RDS root CA certificate from the link available at <u>SSL Support for MySQL DB Instances</u> in the AWS documentation. Download the RDS intermediate CA certificate for the region where the MySQL server resides from the appropriate link available at <u>Intermediate Certificates</u> in the AWS documentation.

If using the root CA certificate results in the error "Path does not chain with any of the trust anchors," then switch to using the intermediate CA certificate.

# SSH Host Key Retrieval and Verification

When Cloudera Director logs into an instance through SSH, by default it does not perform host key verification against the remote host. For added security and to prevent man-in-the middle attacks, host key verification can be enabled by setting the host key fingerprint retrieval type.

The sshHostKeyRetrievalType can be set in the conf file to specify the desired host key fingerprint retrieval type. The allowable values are: NONE, PROVIDER, INSTANCE, and FALLBACK.

#### **NONE**

Cloudera Director will not attempt to retrieve the host key fingerprints for the instances, and host key verification is not performed. This is the default behaviour.

#### **PROVIDER**

Cloudera Director will attempt to retrieve the host key fingerprints for each instance from the cloud provider. This is currently only supported for AWS. This is done in AWS by using the API to read the console output for the instance, which usually displays the host key fingerprints associated with the instance. See <u>Getting Console Output and Rebooting Instances</u> in the AWS documentation for more information on reading the console output. Since Cloudera Director has to wait for the console output to appear, this will increase bootstrap time by around three to five minutes.

Note that not all AMIs display the host key fingerprints for the instance in the console output. Before enabling this, ensure that the AMI displays a section that looks like the following in the console output:

```
ec2: ----BEGIN SSH HOST KEY FINGERPRINTS----
ec2: 1024 6d:99:6d:f1:d5:42:42:68:f1:5b:40:e9:ff:30:82:38 /etc/ssh/ssh_host_dsa_key.pub
(DSA)
ec2: 2048 2d:e1:d3:48:06:0d:32:32:1b:14:3a:87:49:18:ca:2a /etc/ssh/ssh_host_key.pub
(RSA1)
ec2: 2048 7f:1b:3b:51:42:2e:4e:be:9f:f1:77:15:a6:33:62:c7 /etc/ssh/ssh_host_rsa_key.pub
(RSA)
ec2: -----END SSH HOST KEY FINGERPRINTS-----
```

#### INSTANCE

On the first SSH connection into the instance, Cloudera Director will retrieve and store the host key fingerprints by reading the host key files in /etc/ssh. Future SSH connections will be verified using the stored fingerprints. This method is less secure than the PROVIDER method, since the very first SSH connection isn't verified.

### **FALLBACK**

This approach is a combination of PROVIDER and INSTANCE. Cloudera Director will first attempt to retrieve the host key fingerprints from the cloud provider (using PROVIDER method). If that fails or is not supported, it will attempt to retrieve the fingerprints through the instance on the first SSH connection (INSTANCE method).

# Creating Kerberized Clusters With Cloudera Director

Using Cloudera Director 2.0 and higher with Cloudera Manager 5.5.0 and higher, you can create and configure Kerberized Cloudera Manager clusters. To launch a Kerberized cluster, edit the configuration file as described below and launch the cluster with Cloudera Director client, using the bootstrap-remote command to send the configuration file to a running Cloudera Director server.

You must have an existing Kerberos Key Distribution Center (KDC) set up, and it must be reachable by the instance where Cloudera Director server is running and the instances where your Cloudera Manager cluster will be deployed. You must also set up a Kerberos realm for the cluster and a principal in that realm.

Note: To deploy a cluster that connects to a special Kerberos appliance such as FreeIPA, run the following command on the Cloudera Manager host to skip the credential import:

```
sed -i '/kinit/i exit 0' /usr/share/cmf/bin/import_credentials.sh
```

This step is required because Cloudera Manager cannot import the credentials, and the credentials are not necessary in this scenario.

Important: Do not use Cloudera Manager to enable Kerberos on an existing cluster that is managed by Cloudera Director. Kerberos must be enabled through Cloudera Director using the configuration file, at the time of cluster setup.

## Creating a Kerberized Cluster with the Cloudera Director Configuration File

A sample configuration file for creating Kerberized Cloudera Manager clusters is available on the Cloudera GitHub site: director-scripts/kerberos/aws.kerberos.sample.conf.

The settings for enabling Kerberos are in the Cloudera Manager section of the configuration file. Provide values for the following configuration settings:

Configuration setting	Description
krbAdminUsername	An administrative Kerberos account with permissions that allow the creation of principals on the KDC that Cloudera Manager will be using. This is typically in the format principal@your.KDC.realm
krbAdminPassword	The password for the administrative Kerberos account.
KDC_TYPE	The type of KDC Cloudera Manager will use. Valid values are "MIT KDC" and "Active Directory".
KDC_HOST	The hostname or IP address of the KDC.
SECURITY_REALM	The security realm that the KDC uses.
AD_KDC_DOMAIN	Active Directory suffix where all the accounts used by CDH daemons will be created. Used only if Active Directory KDC is being used for authentication. This configuration should be in the format of an X.500 Directory Specification (DC=domain,DC=example,DC=com).
KRB_MANAGE_KRB5_CONF	Set this to true. This allows Cloudera Manager to deploy Kerberos configurations to cluster instances. The value false is not supported for this configuration setting.
KRB_ENC_TYPES	The encryption types your KDC supports. Some of encryption types listed in the sample configuration file require the unlimited strength JCE policy files.

Other Kerberos configuration options are available to Cloudera Manager. For more information, see Configuring Authentication in the Cloudera Security guide.

The following example shows the cloudera-manager section of a configuration file with MIT KDC Kerberos enabled:

```
cloudera-manager {
  instance: ${instances.cm-image} {
     tags {
         application: "Cloudera Manager 5"
   }
 Automatically activate 60-Day Cloudera Enterprise Trial
  enableEnterpriseTrial: true
  unlimitedJce: true
# Kerberos principal and password for use by Cloudera Director
  krbAdminUsername: "principal@my.kdc.realm"
  krbAdminPassword: "password"
# Cloudera Manager configuration values
   configs {
      CLOUDERA_MANAGER {
        KDC_TYPE: "MIT KDC"
         KDC_HOST: "KDC_host_ip_address"
         SECURITY_REALM: "my_security_realm"
         KRB_MANAGE_KRB5_CONF: true
       KRB_ENC_TYPES: "aes256-cts aes128-cts des3-hmac-sha1 arcfour-hmac des-hmac-sha1
des-cbc-md5 des-cbc-crc"
```

# **Enabling Sentry Service Authorization**

This topic describes how to enable the Sentry service with Cloudera Director.

## **Prerequisites**

- Cloudera Director 1.1.x
- CDH 5.1.x (or higher) managed by Cloudera Manager 5.1.x (or higher).
- Kerberos authentication implemented on your cluster.

## Setting Up the Sentry Service Using the Cloudera Director CLI

For this method, you use the Cloudera Director client and the bootstrap-remote command to send a configuration file to the Cloudera Director server to deploy clusters. See <u>Submitting a Cluster Configuration File</u> for more details. Make sure you add SENTRY to the array of services to be launched. This is specified in the configuration file as:

```
services: [HDFS, YARN, ZOOKEEPER, HIVE, OOZIE, HUE, IMPALA, SENTRY]
```

To specify a database, use the databases setting as follows:

```
cluster {
...
databases {
    SENTRY: {
        type: mysql
        host: sentry.db.example.com
        port: 3306
        user: <database_username>
        password: <database_password>
        name: <database_name>
}
```

```
}
```

If you don't include an entry for Sentry in the databases section of the configuration file, the Cloudera Director default database, PostgreSQL, will be used, rather than the Cloudera Manager default database for Sentry, which is MySQL.

The Sentry service also requires the following custom configuration for the MapReduce, YARN, HDFS, Hive, and Impala Services.

 MapReduce: Set the Minimum User ID for Job Submission property to zero (the default is 1000) for every TaskTracker role group that is associated with Hive.

```
MAPREDUCE {
    TASKTRACKER {
        taskcontroller_min_user_id: 0
}
```

• YARN: Ensure that the Allowed System Users property, for every NodeManager role group that is associated with Hive, includes the hive user.

```
YARN {
    NODEMANAGER {
        container_executor_allowed_system_users: hive, impala, hue
}
```

HDFS: Enable HDFS extended ACLs.

```
HDFS
    dfs_permissions: true
    dfs_namenode_acls_enabled: true
}
```

With Cloudera Manager 5.3 and CDH 5.3, you can enable synchronization of HDFS and Sentry permissions for HDFS files that are part of Hive tables. For details on enabling this feature using Cloudera Manager, see Synchronizing **HDFS ACLs and Sentry Permissions.** 

• Hive: Make sure Sentry policy file authorization has been disabled for Hive.

```
HIVE {
    sentry_enabled: false
```

Impala: Make sure Sentry policy file authorization has been disabled for Impala.

```
IMPALA {
    sentry_enabled: false
```

#### Set Permissions on the Hive Warehouse

Once setup is complete, configure the following permissions on the Hive warehouse. For Sentry authorization to work correctly, the Hive warehouse directory (/user/hive/warehouse or any path you specify as hive.metastore.warehouse.dir in your hive-site.xml) must be owned by the Hive user and group.

- Permissions on the warehouse directory must be set as follows:
  - 771 on the directory itself (for example, /user/hive/warehouse)
  - 771 on all subdirectories (for example, /user/hive/warehouse/mysubdir)
  - All files and subdirectories must be owned by hive:hive

## For example:

```
$ sudo -u hdfs hdfs dfs -chmod -R 771 /user/hive/warehouse
 sudo -u hdfs hdfs dfs -chown -R hive:hive /user/hive/warehouse
```

## Setting up the Sentry Service Using the Cloudera Director API

You can use the Cloudera Director API to set up Sentry. Define the ClusterTemplate to include Sentry as a service, along with the configurations specified above, but in JSON format.

Set permissions on the Hive warehouse as described above.

## Related Links

For detailed instructions on adding and configuring the Sentry service, see <u>Installing and Upgrading the Sentry Service</u> and Configuring the Sentry Service.

Examples on using Grant/Revoke statements to enforce permissions using Sentry are available at Hive SQL Syntax.

# Creating Highly Available Clusters With Cloudera Director

Using Cloudera Director 2.0 or higher and Cloudera Manager 5.5 or higher, you can launch highly available clusters for HDFS, YARN, ZooKeeper, HBase, Hive, Hue, and Oozie. The services are highly available on cluster launch with no additional setup. To enable high availability, edit the Cloudera Director configuration file as described in this topic and launch the cluster with the Cloudera Director client and the bootstrap-remote command, which sends the configuration file to a running Cloudera Director server.

Note: With Cloudera Director 1.5 and Cloudera Manager 5.4, you can set up a highly available cluster by running a script after the cluster is launched. For more information, see the high-availability scripts and the README file on the Cloudera Director GitHub site.

#### Limitations and Restrictions

The following limitations and restrictions apply to creating highly available clusters with Cloudera Director:

- The procedure described in this section works with Cloudera Director 2.0 or higher and Cloudera Manager 5.5 or higher.
- Cloudera Director does not support migrating a cluster from a non-high availability setup to a high availability
- Cloudera recommends sizing the master nodes large enough to support the desired final cluster size.
- Settings must comply with the configuration requirements described below and in the aws.ha.reference.conf file. Incorrect configurations can result in failures during initial bootstrap.

## Editing the Configuration File to Launch a Highly Available Cluster

Follow these steps to create a configuration file for launching a highly available cluster.

- 1. Download the sample configuration file <u>aws.ha.reference.conf</u> from the Cloudera GitHub site. The cluster section of the file shows the role assignments and required configurations for the services where high availability is supported. The file includes comments that explain the configurations and requirements.
- 2. Copy the sample file to your home directory before editing it. Rename the aws.ha.reference.conf file, for example, to ha.cluster.conf. The configuration file must use the .conf file extension. Open the configuration file with a text editor.

Note: The sample configuration file includes configuration specific to Amazon Web Services, such as the section for cloud provider credentials. The file can be modified for other cloud providers by copying sections from the other cloud provider-specific sample files, for example, gcp.simple.conf.

3. Edit the file to supply your cloud provider credentials and other details about the cluster. A highly available cluster has additional requirements, as seen in the sample aws.ha.reference.conf file. These requirements include duplicating the master roles for highly available services.

The sample configuration file includes a set of instance groups for the services where high availability is supported. An instance group specifies the set of roles that are installed together on an instance in the cluster. The master roles in the sample aws.ha.reference.conf file are included in four instance groups, each containing particular roles. The names of the instance groups are arbitrary, but the names used in the sample file are hdfsmasters-1, hdfsmasters-2, masters-1, and masters-2. You can create multiple instances in the cluster by setting the value of the count field for the instance group. The sample file is configured for two hdfsmasters-1 instances, one hdfsmasters-2 instance, two masters-1 instances, and one masters-2 instance.

The cluster services for which high availability is supported are listed below, with the minimum number of roles required and other requirements.

- HDFS
  - Two NAMENODE roles.
  - Three JOURNALNODE roles.
  - Two FAILOVERCONTROLLER roles, each colocated to run on the same host as one of the NAMENODE roles (that is, included in the same instance group).
  - One HTTPFS role if the cluster contains a Hue service.
  - The NAMENODE nameservice, autofailover, and quorum journal name must be configured for high availability exactly as shown in the sample aws.ha.reference.conf file.
  - Set the HDFS service-level configuration for fencing as shown in the sample aws.ha.reference.conf file:

```
configs {
                # HDFS fencing should be set to true for HA configurations
                dfs_ha_fencing_methods: "shell(true)"
```

 Three role instances are required for the HDFS JOURNALNODE role. This ensures a quorum for determining which is the active node and which are standbys.

For more information, see <u>HDFS High Availability</u> in the Cloudera Administration documentation.

- YARN
  - Two RESOURCEMANAGER roles.
  - One JOBHISTORY role.

For more information, see YARN (MRv2) ResourceManager High Availability in the Cloudera Administration documentation.

- ZooKeeper
  - Three SERVER roles (recommended). There must be an odd number, but one will not provide high availability
  - Three role instances are required for the ZooKeeper SERVER role. This ensures a quorum for determining which is the active node and which are standbys.
- HBase
  - Two MASTER roles.

For more information, see HBase High Availability in the Cloudera Administration documentation.

### Security, Encryption, and High Availability

- Hive
  - Two HIVESERVER2 roles.
  - Two HIVEMETASTORE roles.

For more information, see Hive Metastore High Availability in the Cloudera Administration documentation.

- Hue
  - Two HUESERVER roles.
  - One HTTPFS role for the HDFS service.
  - One HUE\_LOAD\_BALANCER role

For more information, see <u>Hue High Availability</u> in the Cloudera Administration documentation.

- Oozie
  - Two SERVER roles.
  - Oozie plug-ins must be configured for high availability exactly as shown in the sample aws.ha.reference.conf file. In addition to the required Oozie plug-ins, other Oozie plug-ins can be enabled. All Oozie plug-ins must be configured for high availability.
  - Oozie requires a load balancer for high availability. Cloudera Director does not create or manage the load balancer. The load balancer must be configured with the IP addresses of the Oozie servers after the cluster completes bootstrapping.

For more information, see Oozie High Availability in the Cloudera Administration documentation.

- The following requirements apply to databases for your cluster:
  - You can configure external databases for use by the services in your cluster and for Cloudera Director. If no databases are specified in the configuration file, an embedded PostgreSQL database is used.
  - External databases can be set up by Cloudera Director, or you can configure preexisting external databases to be used. Databases set up by Cloudera Director are specified in the databaseTemplates block of the configuration file. Preexisting databases are specified in the databases block of the configuration file. External databases for the cluster must be either all preexisting databases or all databases set up by Cloudera Director; a combination of these is not supported.
  - Hue, Oozie, and the Hive metastore each require a database.
  - Databases for highly available Hue, Oozie, and Hive services must themselves be highly available. An Amazon RDS MySQL Multi-AZ deployment, whether preexisting or configured to be created by Cloudera Director, satisfies this requirement.

#### Using Role Migration to Repair HDFS Master Role Instances

Cloudera Director supports exact one-for-one host replacement for HDFS master role instances. This is a partially manual process that requires migration of the roles in Cloudera Manager. If a host running HDFS master roles (NameNode, Failover Controller, and JournalNode) fails in a highly available cluster, you can use Cloudera Director and the Cloudera Manager Role Migration wizard to move the roles to another host without losing the role states, if any. The previously standby instance of each migrated role runs as the active instance. When the migration is completed, the role that runs on the new host becomes the standby instance.

Keep in mind the following when performing HDFS role migration:

- Do not modify any instance groups on the cluster during the repair and role migration process.
- Do not clone the cluster during the repair and role migration process.
- <u>Instance-level post-creation scripts</u> will not be run on any instances that are part of a manual migration. If you have instance-level post-creation scripts and want them to run during manual migration, run the scripts manually.
- To complete the migration (Step 3 below), click a checkbox to indicate that the migration is done, after which the old instance is terminated. Check Cloudera Manager to ensure that the old host has no roles or data on it before performing this step in Cloudera Director. Once the old instance is terminated, any information or state it contained is lost.

 If you have completed Step 1 (on Cloudera Director) and intend to complete Step 2 (on Cloudera Manager) at a later time, you can confirm which IP address to migrate from or to by going to the cluster status page in Cloudera Director and clicking either the link for migration in the upper left, or the Modify Cluster button on the right. A popup displays the hosts to migrate from and to:

# Manual Role Migration Attention! The following instances have master roles that need to be manually migrated from within Cloudera Manager: Migrate the roles by using Cloudera Manager commands I have manually migrated these roles Original Instance **New Instance Roles to Migrate** 178.28.5.37 178.28.4.199 ZooKeeper: Server HDFS: NameNode, Failover Controller, JournalNode Ignore for now, I will complete manual role migration later

- You do not need to check the boxes to restart and deploy client configuration at the start of the repair process. You restart and deploy the client configuration manually after role migration is complete.
- Do not attempt repair for non-highly available master roles. The Cloudera Manager Role Migration wizard only works for high availability HDFS roles.

#### Step 1: In Cloudera Director, Create a New Instance

- 1. In Cloudera Director, click the cluster name and click **Modify Cluster**.
- 2. Click the checkbox next to the IP address of the failed instance (containing the HDFS NameNode and colocated Failover Controller, and possibly a JournalNode). Click Repair.
- 3. Click OK. You do not need to select Restart Cluster at this time, because you will restart the cluster after migrating the HDFS master roles.

Cloudera Director creates a new instance on a new host, installs the Cloudera Manager agent on the instance, and copies the Cloudera Manager parcels to it.

## Step 2: In Cloudera Manager, Migrate Roles and Data

Open the cluster in Cloudera Manager. On the Hosts tab, you see a new instance with no roles. The cluster is in an intermediate state, containing the new host to which the roles will be migrated and the old host from which the roles will be migrated.

Use the Cloudera Manager Migrate Roles wizard to move the roles.

See Moving Highly Available NameNode, Failover Controller, and JournalNode Roles Using the Migrate Roles Wizard in the Cloudera Administration guide.

## Step 3: In Cloudera Director, Delete the Old Instance

- 1. Return to the cluster in Cloudera Director.
- 2. Click Details. The message "Attention: Cluster requires manual role migration" is displayed. Click More Details.
- 3. Check the box labeled, "I have manually migrated these roles."
- 4. Click OK.

The failed instance is deleted from the cluster.

# Configuring and Running Cloudera Director

The topics in this section explain how to configure and run Cloudera Director.

## Auto-Repair for Failed or Terminated Instances

Cloudera Director 2.5 and higher with Cloudera Manager 5.12 or higher includes an auto-repair feature that allocates new cluster instances to replace failed or terminated instances. For clusters running on AWS, this includes Spot instances that were terminated by Amazon because your bid price became lower than Amazon's current Spot instance price. Auto-repair checks to ensure that the number of instances in your cluster matches the number that was specified in the cluster template.

Note: If auto-repair is enabled on a cluster that uses Elastic Block Storage (EBS), you must disable auto-repair for the cluster before stopping either the cluster or the Cloudera Manager instance that manages it. For information about stopping and starting clusters that use EBS volumes, see Using EBS Volumes for Cloudera Manager and CDH on page 145.

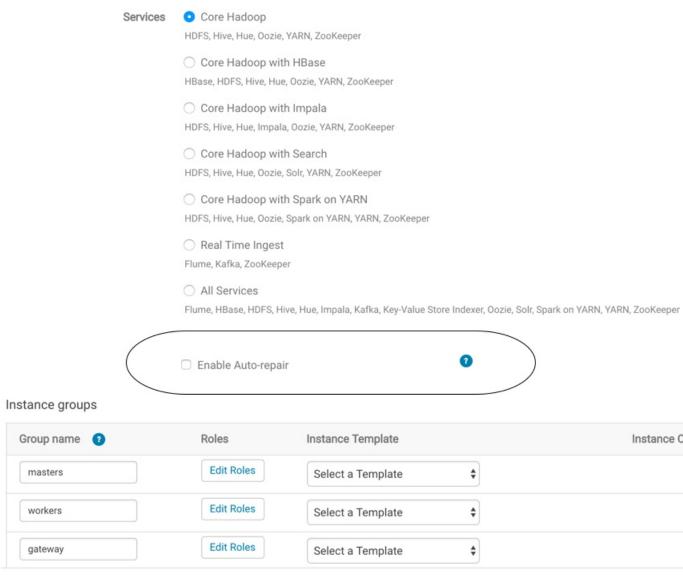

Note: Do not use auto-repair on Microsoft Azure with Cloudera Director 2.6 and higher. Healthy instances can sometimes be removed when there is a connection failure between Cloudera Director and Azure.

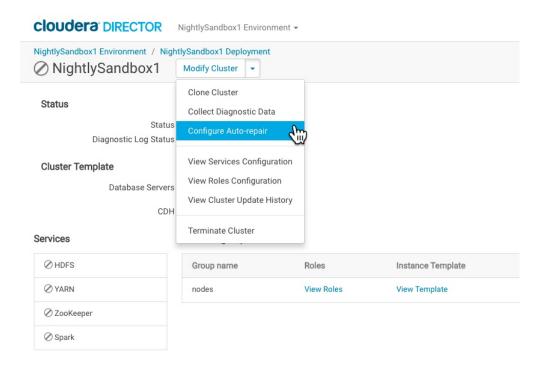

By default, auto-repair is not enabled. You can enable auto-repair in one of the following three ways:

• During the installation process while configuring settings for the cluster:

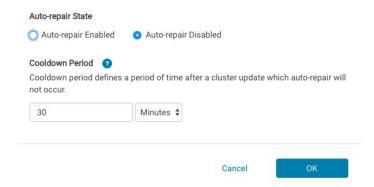

## Configuring and Running Cloudera Director

• In the Modify Cluster dropdown for an existing cluster:

Choosing **Configure Auto-repair** in the **Modify Cluster** drop-down opens a dialog for enabling or disabling the auto-repair feature or configuring the cooldown period, which is the time that elapses between Cloudera Director's attempts to allocate new cluster instances:

• If you are launching a cluster with the bootstrap-remote CLI command and a configuration file, you can enable auto-repair by setting autoRepairEnabled to true in the administrationSettings section of the configuration file:

```
administrationSettings {
    # If enabled, Director will attempt to automatically repair
    # clusters whose instances have been terminated in the cloud provider.

# autoRepairEnabled: false
    # autoRepairCooldownPeriodInSeconds: 1800
}
```

Keep in mind the following facts about the auto-repair feature:

- Auto-repair is only available with Cloudera Director 2.5 and higher running with Cloudera Manager 5.12 and higher.
- Auto-repair only functions with instances that do not contain master roles.
- Before stopping a cluster using the Elastic Block Storage (EBS) start/stop feature, you must disable auto-repair if it is enabled.
- Auto-repair is disabled by default, and can be enabled (1) when creating a cluster in the web UI, (2) on the web UI page for an existing cluster, or (3) in the configuration file when launching a cluster with bootstrap-remote.

- Auto-repair is only available for clusters managed with Cloudera Director server; the feature is not available for clusters running in the standalone client version of Cloudera Director.
- Auto-repair will attempt to allocate the same type of instance that is missing from the cluster. So for an on-demand instance, another on-demand instance with identical specifications will be allocated. For a Spot instance, another Spot instance with the same bid price will be allocated.
- The auto-repair cooldown period ensures that, even if auto-repair is enabled and your cluster has fewer instances than specified in the cluster template, Cloudera Director will not continuously attempt to repair the cluster, and you will therefore have frequent intervals when you can interact with the cluster to perform other tasks. The cooldown period is configurable in the web UI or the configuration file.

# Deploying a Java 8 Cluster

When you install Cloudera Manager and CDH clusters in the cloud with Cloudera Director, a version of the Java JDK is installed on each instance during the bootstrap process. By default, Cloudera Director installs a version of Java 7, but Java 8 can be installed, instead, by running the bootstrap script described on this page.

## javaInstallationStrategy configuration

In order to use this bootstrap script, you must configure your deployment to use a javaInstallationStrategy value of NONE. This can be done using a configuration file or using the Cloudera Director API, but this property is not currently configurable in the Cloudera Director web UI. Here is how this setting would look in a configuration file:

```
cloudera-manager {
    instance: ${instances.m3x} {
        tags {
            application: "Cloudera Manager 5"
    javaInstallationStrategy: NONE
}
```

After the Cloudera Manager deployment has been created, additional Java 8 clusters can be added from the web web UI using the bootstrap script.

## Bootstrap script

The bootstrap script java8-bootstrap-script.sh is located on the Cloudera public GitHub site. Also on the site is a copy of the instructions for using the script, **Deploying a Java 8 cluster**.

Use java8-bootstrap-script.sh as the bootstrap script for the instance templates in your cluster. This will install Java 8, which will be used to run Cloudera Manager and all of the cluster services. The following example shows how this might look in a configuration file:

```
instances {
        type: m3.xlarge
        image: ami-6283a827
        bootstrapScriptsPaths: ["/script-path/java8-bootstrap-script.sh"]
}
```

Alternatively, you can copy the contents of the bootstrap script itself and use the bootstrapScript property instead.

Note: The URL in the script refers to CentOS/RHEL 7 and Cloudera Director 2.1.0. Update the URL to a different version of CentOS/RHEL if necessary, depending on what operating system your cluster instances will run.

# **Setting Cloudera Director Properties**

This topic lists the configuration properties recognized by Cloudera Director. Upon installation, these properties are pre-configured with reasonable default values, and you can run either client or server versions without specifying any of them. However, you might want to customize one or more properties, depending on your environment and the Cloudera Director features you want to use.

#### **Setting Configuration Properties**

The Cloudera Director command line provides the simplest way to specify a configuration property. For example:

```
./bin/cloudera-director bootstrap aws.simple.conf \
--lp.pipeline.retry.maxWaitBetweenAttempts=60

./bin/cloudera-director-server --lp.security.disabled=false
```

#### Tip: If you want to configure many properties, add them to the

/etc/cloudera-director-client/application.properties file (for the standalone client) or the /etc/cloudera-director-server/application.properties (for the server) in the Cloudera Director installation. Any changed properties in these files take effect automatically when Cloudera Director is restarted. To override existing properties, set new values in the command line.

While the application.properties files are located on the Cloudera Director EC2 instance at /etc/cloudera-director-client/application.properties for the client, and /etc/cloudera-director-server/application.properties, you can see an example of the files on Cloudera's GitHub site, showing the configuration properties.

#### For users upgrading Cloudera Director

If you modified the application.properties file in Cloudera Director, the result of an upgrade depends on the version of Linux you are using:

- RHEL and CentOS When new properties are introduced in Cloudera Director, they are added to application.properties.rpmnew. The original application.properties file functions as before and is not overwritten with the new Cloudera Director version properties. You do not need to copy the new properties from application.properties.rpmnew to the old application.properties file.
- **Ubuntu** The modified Cloudera Director application.properties file is backed up to a file named application.properties.dpkg-old. The original application.properties file is then overwritten by the new application.properties file containing new Cloudera Director properties. After upgrading, copy your changes from application.properties.dpkg-old to the new application.properties file.

All the new properties are commented, and they all use valid defaults, so you do not necessarily need to merge the two properties files. But you must merge the two files if you want to modify one of the newly introduced properties.

#### **Property Types**

Туре	Description
boolean	Either true or false
char	Single character
directory	Valid directory path
enum	Fixed set of string values; a list of each enumeration's values is provided following the main property table below
enum list	Comma-separated list of enums
file	Valid file path

Туре	Description
int	Integer (32-bit)
long	Long integer (64-bit)
string	Ordinary character string
time unit	Enumeration of time units: DAYS, HOURS, MICROSECONDS, MILLISECONDS, MINUTES, NANOSECONDS, SECONDS

## Pausing Cloudera Director Instances

The Cloudera Director server can be stopped at any time to reduce costs, as can clusters running on Microsoft Azure. These actions are described in the sections below.

## Pausing the Cloudera Director Server

Although you can stop and start the Cloudera Director server at any time, you should wait for running workflows to complete.

To start or stop the server, enter the following command:

\$ sudo service cloudera-director-server [start | stop]

## Pausing a Cluster in Azure

There are times when it makes sense to shut down a cluster and stop your Azure virtual machines. The cluster will not be immediately available while stopped and it cannot be used to ingest or process data, but you won't be billed by Microsoft for virtual machines that are stopped and deallocated. Provisioned premium storage disks, and space used by standard storage disks will continue to accrue charges.

Pausing a cluster requires using premium or standard storage disks for all storage, both on management and worker nodes. Data stored on ephemeral disks will be lost after a cluster pause.

Pausing a cluster also requires that the private IP address for all Azure Virtual Machines be set to static.

#### Notes on Pausing a Cluster

Important: Azure virtual machines that are configured with static private IP addresses will retain their internal IP address and hostname as long as the associated network interface object is not removed, so no reconfiguration of CDH is required after restart. If your nodes were provisioned via Cloudera Director, you should confirm that the IP configuration of your hosts is set to static before shutting down your cluster. The default for the Cloudera Director Azure plugin is dynamic. If you need to change the IP configuration from dynamic to static it can be done via the Azure Portal or PowerShell.

Note: The Microsoft Azure Portal, CLI, or API can be used for Azure actions; shutting down the virtual machine locally with the **shutdown** command will leave the virtual machine in a billable state. The Cloudera Manager UI or start and stop API commands can be used for cluster actions.

### Shutdown procedure

To pause the cluster, take the following steps:

- 1. Change all virtual machine's private IP address from dynamic to static by following the instructions in the Important note paragraph above in Notes on Pausing a Cluster.
- 2. Stop the cluster
- 3. Stop Cloudera Management Service

### Configuring and Running Cloudera Director

4. Stop all cluster virtual machines, including the Cloudera Manager host

#### Startup procedure

To restart the cluster after a pause, the steps are reversed:

- 1. Start all cluster virtual machines
- 2. Start Cloudera Management Service
- **3.** Start the cluster

Since the cluster was completely stopped before stopping the virtual machines, the cluster should be healthy upon restart and ready for use.

#### Considerations

After starting the virtual machines, Cloudera Manager and its agents will be running but the cluster will be stopped. There will be gaps in Cloudera Manager's time-based metrics and charts.

Dynamic public IP addresses will be different after virtual machine shutdown. Static public IP addresses can be configured to remain associated with a stopped virtual machine at additional cost, but it isn't necessary to maintain proper cluster operation.

# Configuring Cloudera Director for a New AWS Instance Type

Amazon Web Services occasionally introduces new instance types with improved specifications. Cloudera Director ships with the functionality needed to support all of the instance types available at the time of release, but customers can augment that to allow it to support new types that are introduced after release.

## **Updated Virtualization Mappings**

Each Linux Amazon Machine Image (AMI) uses one of two types of virtualization, paravirtual or HVM. Cloudera Director ensures that the instance type of an instance that is to host an AMI supports the AMI's virtualization type. The knowledge of which instance types support which virtualizations resides in a virtualization mappings file.

The AWS plugin included with Cloudera Director ships with an internal mappings file for all instance types that are available at the time of release. You can add new mappings, or override existing mappings, by creating another custom mappings file. Only new or changed mappings need to be included in the custom mappings file.

The standard location for the custom mappings file is etc/ec2.virtualizationmappings.properties under the AWS plugin directory. An example file is provided in the etc directory as a basis for customization. You can provide a different location to Cloudera Director by by adding the following section to etc/aws-plugin.conf:

```
virtualizationMappings {
    customMappingsPath: ec2.customvirtualizationmappings.properties
```

If the property is a relative path, it is based on the etc directory under the AWS plugin directory.

Here is an example of a custom mappings file that adds the new "d2" instance types introduced in AWS at the end of March 2015. These new instance types only support HVM virtualization. To keep the example short, many instance types are omitted; in an actual custom mappings file, each property value must provide the full list of instance types that support the property key and virtualizaton type.

```
hvm=m3.medium, \
m3.large,\
m3.xlarge,
m3.2xlarge,\
 d2.xlarge,\
 d2.2xlarge,\
 d2.4xlarge,\
 d2.8xlarge
```

To learn more about virtualization types, see <u>Linux AMI Virtualization Types</u> in the AWS documentation.

## Updated Ephemeral Device Mappings

Each AWS instance type provides zero or more instance store volumes, also known as ephemeral storage. These volumes are distinct from EBS-backed storage volumes; some instance types include no ephemeral storage. Cloudera Director specifies naming for each ephemeral volume, and keeps a list of the number of such volumes supported per instance type in an ephemeral device mappings file.

The AWS plugin included with Cloudera Director ships with an internal mappings file for all instance types that are available at the time of release. You can add new mappings, or override existing mappings, by creating another custom mappings file. Only new or changed mappings need to be included in the custom mappings file.

The standard location for the custom mappings file is etc/ec2.ephemeraldevicemappings.properties under the AWS plugin directory. An example file is provided in the etc directory as a basis for customization. You can provide a different location to Cloudera Director by by adding the following section to etc/aws-plugin.conf:

```
ephemeralDeviceMappings {
    customMappingsPath: ec2.customephemeraldevicemappings.properties
```

If the property is a relative path, it is based on the etc directory under the AWS plugin directory.

Here is an example of a custom mappings file that describes the new "d2" instance types introduced at the end of March 2015. These new instance types each support a different number of instance store volumes.

```
d2.xlarge=3
d2.2xlarge=6
d2.4xlarge=12
d2.8xlarge=24
```

To learn more about ephemeral storage, including the counts for each instance type, see Instance Stores Available on Instance Types in the AWS documentation.

#### Using the New Mappings

Once the custom mappings files have been created, restart the Cloudera Director server so that they are detected and overlaid on the built-in mappings.

New instance types do not automatically appear in drop-down menus in the Cloudera Director web interface. However, the selected values for these menus may be edited by hand to specify a new instance type.

# Configuring Cloudera Director to Use Custom Tag Names on AWS

In addition to user-specified tags, Cloudera Director automatically adds certain tags to the AWS resources it creates, including EC2 and RDS instances, EBS volumes, and Spot instance requests. Where applicable, the added tags include the resource name, the unique identifier that Cloudera Director assigns to the resource, and the name of the template that was used to create the resource.

In some environments, the tag names that Cloudera Director uses may conflict with tag names used for other purposes, so it is possible to customize the tag names. To do so, add the following section to etc/aws-plugin.conf:

```
customTagMappings {
   Name: custom-tag-name-for-resource-name,
   Cloudera-Director-Id: custom-tag-name-for-resource-id,
   Cloudera-Director-Template-Name: custom-tag-name-for-resource-template-name
}
```

## Configuring and Running Cloudera Director

## Using the New Mappings

Once the custom tag mappings have been added to the configuration file, restart the Cloudera Director server so that they are detected and used.

Note: If you have existing resources created by Cloudera Director using the default tag mappings, Cloudera Director will not be able to use their tags correctly once it restarts with the custom tag mappings. You should shut down the Cloudera Director server, update the tags manually using the AWS console or CLI, and then start the Cloudera Director server again.

The Cloudera Director server is designed to run in a centralized setup, managing multiple Cloudera Manager instances and CDH clusters, with multiple users and user accounts. The server works well for launching and managing large numbers of clusters in a production environment. Cloudera Director server configuration and use are described in the following topics.

# Cloudera Director and Cloudera Manager Usage

Cloudera Director works with Cloudera Manager and the cloud service provider to provide centralized and programmatic administration of clusters in the cloud, including deployment, configuration, and maintenance of CDH clusters. With Cloudera Director, you can monitor and manage multiple Cloudera Manager and CDH deployments, across different cloud environments.

When you use Cloudera Director to deploy CDH, you can perform administrative tasks either in Cloudera Director or in Cloudera Manager. To avoid conflicts and inconsistencies, use the management tool most appropriate for the task.

 With Cloudera Director 2.4 and higher and Cloudera Manager and CDH 5.11 and higher, many changes made directly in Cloudera Manager are detected by Cloudera Director, which periodically refreshes its state to reflect the state of the cluster in Cloudera Manager. Cloudera Director also refreshes its stored templates for the cluster so that your updated configuration is used if you create more instances or clone the cluster.

Note: After making modifications in Cloudera Manager, wait at least five minutes for Cloudera Director to refresh before making any cluster modifications in Cloudera Director-side cluster modifications, such as grow or shrink.

 With Cloudera Director 2.3 and lower or Cloudera Manager and CDH 5.10 or lower, if you perform certain administrative tasks in Cloudera Manager, Cloudera Director and Cloudera Manager will become out of sync. When Cloudera Director and Cloudera Manager are out of sync, Cloudera Director cannot grow or shrink the cluster or perform other updates to the cluster. You can use Cloudera Director 2.3 and lower to deploy new Cloudera Manager instances and clusters, but Cloudera Manager instances that are out of sync with Cloudera Director will function independently of Cloudera Director.

### When to Use Cloudera Director

Use Cloudera Director when you want to perform the following types of tasks:

- Deploying Cloudera Manager and CDH clusters for prototyping.
- Deploying Cloudera Manager and CDH clusters when you have finalized the topology and configuration.
- Growing or shrinking a cluster. If you have made changes to the cluster using Cloudera Manager, update Cloudera Director with the changes and redeploy the cluster before you grow or shrink the cluster.
- Setting up clusters with Kerberos authentication or high availability.

## When to Use Cloudera Manager

Use Cloudera Manager when you want to perform the following types of tasks:

- Adding or removing a service in an existing cluster.
- · Changing role assignments for an existing virtual instance group, or migrate roles from one instance to another
- Changing the configuration of a service or role
- Testing and iterating on the topology and configuration of clusters.

Use Cloudera Director to create the cluster when you have finalized the topology and configuration.

## **CDH Cluster Management Tasks**

When you deploy CDH and Cloudera Manager through Cloudera Director, you use Cloudera Director or Cloudera Manager to manage the clusters, depending on the task.

The following table lists cloud administrative tasks and the application where you must perform them to avoid inconsistencies in Cloudera Director and Cloudera Manager:

Task	Application	Notes
Cluster setup	Cloudera Director	Cloudera Director cannot manage clusters that are set up directly in Cloudera Manager.
Addition of host to a cluster or addition of cluster to Cloudera Manager	Cloudera Director	
Host decommission	Cloudera Director	This is done by deleting the instance from the virtual instance group using Cloudera Director.
Adding a service	Cloudera Manager	If you add a service to a cluster in Cloudera Manager, Cloudera Director will detect the change and will update its cluster template to match.
Removing a service	Cloudera Manager	If you remove a service from a cluster in Cloudera Manager, Cloudera Director will detect the change and will update its cluster template to match.
		You can stop a service instead of removing it from a cluster. You can also use the grow and shrink feature of Cloudera Director to create hosts that do not have that service's roles.
Initial role assignment	Cloudera Director	
Add new virtual instance groups to a cluster	Cloudera Director	
Change role assignments for an existing virtual instance group, or migrate roles from one instance to another	Cloudera Manager	Cloudera Director periodically refreshes its data on the state of cluster roles in existing virtual instance groups to include changes made with Cloudera Manager. The changes must not result in inconsistency with respect to the roles included in different instances of the same virtual instance group. See <a href="Ensuring Consistency of Virtual InstanceGroups">Ensuring Consistency of Virtual InstanceGroups</a> on page 184 below for more information.
Changes to the configuration of a service or role	Cloudera Manager	Cloudera Director will detect service and role configuration changes made in Cloudera Manager and will update the cluster template and instance templates to match. The changes must not result in inconsistency with respect to the roles included in different instances of the same virtual instance group. See <a href="Ensuring Consistency of Virtual Instance Groups">Ensuring Consistency of Virtual Instance Groups</a> on page 184 below for more information.
Cloud provider settings for instances, such as the machine image or instance type	Cloud provider management tool	Cloudera Director will detect configuration changes made in the cloud provider, including changes in the instance type and machine image, and will update the cluster template and instance templates to match. The changes must not result in inconsistency with respect to the cloud provider configuration included in different instances of the same virtual

Task	Application	Notes
		instance group. In AWS, for example, you can change the AMI or instance type directly in the AWS management console, but you must change all instances in the instance group to be identical. See <a href="Ensuring Consistency of Virtual Instance Groups">Ensuring Consistency of Virtual Instance Groups</a> on page 184 below for more information.
Adding, removing, and modifying parcels	Cloudera Manager	If you activate or deactivate parcels in Cloudera Manager, Cloudera Director will detect this change and update its cluster template to match. Parcel version changes will also be detected. Note that when deactivating a parcel in Cloudera Manager, the associated services for that parcel should also be removed through Cloudera Manager.
Cloudera Manager username and password change	Cloudera Manager and Cloudera Director	Change the username and password in Cloudera Manager. After you change the username and password in Cloudera Manager, you must update the information in Cloudera Director. If you do not update the information in Cloudera Director, Cloudera Director will not be able to monitor or modify the cluster.
Upgrading a Cloudera Manager license	Cloudera Manager	Use Cloudera Manager to upgrade from Cloudera Express to Cloudera Enterprise.  Cloudera Director will not display the state of the updated license, but will not prevent Cloudera Enterprise functionality.
Minor version upgrade to Cloudera Manager or CDH	Cloudera Manager	You must upgrade Cloudera Manager manually and then use the upgraded Cloudera Manager to upgrade CDH.  Cloudera Director will detect the version changes,
		and new clusters will use the upgraded versions.
Enabling high availability during cluster setup	Cloudera Director	High availability is supported in Cloudera Director version 2.0 or higher. Use the configuration file to enable high availability. Do not use the Cloudera Director web UI.

Task	Application	Notes	
Enabling high availability in an existing cluster	Cloudera Manager	Note: When Cloudera Director 2.4 and higher refreshes a cluster to incorporate changes made in Cloudera Manager, it detects changes made at the role group level, but it does not detect configuration changes made at the role instance level. In some cases with Cloudera Manager 5.11 and earlier, the Cloudera Manager high availability (HA) wizard introduces role instance level configuration changes, and these must be moved manually to role group configurations in Cloudera Manager to keep Cloudera Director in sync. This is not an issue if you are using Cloudera Manager 5.12 and higher.	
Modifying a cluster in a highly available deployment	Cloudera Director	If you enable high availability in Cloudera Manager, you can run modify operations only on instance groups that do not contain highly available master roles.	
Enabling Kerberos authentication during cluster setup	Cloudera Director	Kerberos setup is supported in Cloudera Director version 2.0 or higher. Use the configuration file to enable Kerberos during cluster setup. After the cluster is created, the configuration file can no longe be used to enable Kerberos. Do not use the Clouders Director web UI.	
		If you use Cloudera Director to deploy a cluster but use Cloudera Manager to enable Kerberos authentication, Cloudera Director and Cloudera Manager will become out of sync.	

## **Ensuring Consistency of Virtual Instance Groups**

All instances in a virtual instance group must have identical roles assigned to them, with identical role configurations, in order to enable cluster modifications in Cloudera Director. When using Cloudera Director 2.4 and above with Cloudera Manager and CDH 5.11 and above, you can change role assignments, role configurations, and cloud provider settings in Cloudera Manager, but you must ensure that all instances in a given virtual instance group are configured identically. Cloudera Director will then propagate any changes you make in Cloudera Manager back into the cluster's instance templates.

If you make changes to an instance that create role assignments or configurations different from those of other instances in the virtual instance group, Cloudera Director will detect the inconsistency and will flag the virtual instance group in the Cloudera Director UI, identifying which instance is inconsistent what the inconsistencies are. You will not be able to grow that instance group until the inconsistency is fixed.

There are two ways to fix inconsistencies in a virtual instance group:

• In Cloudera Manager, assign or remove roles in the instances that are flagged as inconsistent so that they are identical to the other instances in the virtual instance group

In Cloudera Director, shrink the virtual instance group to remove the instances that are flagged as inconsistent

## CDH Cluster Management Guidelines for Cloudera Director

When you use Cloudera Director to deploy Cloudera Manager and CDH, the cluster information is saved in the Cloudera Director database. If you make changes to the cluster using the cloud provider management console, the changes are detected by Cloudera Director. But terminating an instance using the cloud provider management console results in poor health of the hosts and services in Cloudera Director. If the health of an instance turns bad or the instance fails, you can migrate to a new instance. Use the Cloudera Director web UI to shrink and grow the worker nodes and migrate the master node to a new instance.

For information about growing or shrinking a cluster, see Modifying the Number of Instances in an Existing Cluster on page 212.

For information about migrating HDFS master roles to a new instance, see <u>Using Role Migration to Repair HDFS Master</u> Role Instances on page 170.

# **Setting Cloudera Manager Configurations**

You can use Cloudera Director to set configurations for the various Cloudera Manager entities that it deploys:

- Cloudera Manager
- Cloudera Management Service
- · CDH components such as HDFS, Hive, and HBase
- Role types, such as NameNode, ResourceManager, and Impala Daemon

This functionality is available for both Cloudera Director client and Cloudera Director server:

- Client Using the configuration file.
- Server Using the Cloudera Director web UI or APIs (Java, REST, or Python).
  - To use the REST API, you can submit JSON documents to the REST service endpoint, or access the API console at http://director-server-hostname:7189/api-console.
  - You can find information about the Cloudera Director Java and Python APIs on the director-sdk GitHub page.
  - In the web UI, you can specify custom values for Cloudera Manager configurations when adding an environment or creating a Cloudera Manager cluster.

Note: Cloudera Manager configuration properties are case-sensitive. To verify the correct way to specify Cloudera Manager configuration properties in Cloudera Director API calls and in the configuration name fields of the Cloudera Director web UI, see Cloudera Manager Configuration Properties in the Cloudera Manager documentation. By expanding this heading, you see topics such as the following:

- CDH 5.12.0 Properties
- Host Configuration Properties
- Cloudera Manager Server Properties
- Cloudera Management Service

These pages include tables of configuration properties. Locate the property whose value you want to customize, and use the name in the column API Name.

Cloudera Director enables you to customize deployment and cluster setup, and configurations are applied on top of Cloudera Manager default and automatic host-based configuration of services and roles. Set configurations either in the deployment template or in the cluster template.

## Cluster Configuration Using Cloudera Manager

Some configuration changes can safely be made to Cloudera Director-managed clusters using Cloudera Manager directly. For these use cases, Cloudera Director will sync up automatically with changes made in Cloudera Manager. Other configuration changes cannot be safely made using Cloudera Manager directly because Cloudera Director will not become aware of the change, resulting in failures when a user later tries to expand or otherwise modify the cluster.

For information on configuration changes and other changes to clusters that can and cannot be safely made directly through Cloudera Manager, see <u>Cloudera Director and Cloudera Manager Usage</u> on page 181.

### Setting up a Cloudera Manager License

There are three ways to set up a Cloudera Manager license using Cloudera Director, each corresponding to a field within the Licensing configuration section of the aws.conf configuration file. The three are mutually exclusive.

- **license field** You can embed license text in the license field of the configuration file. (Cloudera recommends using triple quotes (""") for including multi-line text strings, as shown in the commented-out lines of the configuration file.) To embed a license in the license field, find the Licensing configuration section of the configuration file and enter the appropriate values.
- licensePath field The licensePath field can be used to specify the path to a file containing the license.
- enableEnterpriseTrial field The enableEnterpriseTrial flag indicates whether the 60-Day Cloudera Enterprise Trial should be activated when no license is present. This must *not* be set to true if a license is included using either license or licensePath.

The License configuration section of the configuration file is shown below:

```
#
 Embed a license for Cloudera Manager
# license: """
 ----BEGIN PGP SIGNED MESSAGE----
#
 Hash: SHA1
#
#
  "version" : 1,
 "name" : "License Owner",
#
 "uuid" : "license id",
#
  "expirationDate" : 0,
#
 "features" : [ "FEATURE1", "FEATURE2" ]
#
#
 ----BEGIN PGP SIGNATURE----
#
 Version: GnuPG v1.4.11 (GNU/Linux)
# PGP SIGNATURE
#
 ----END PGP SIGNATURE----
#
#
 Include a license for Cloudera Manager from an external file
#
# licensePath: "/path/to/license.txt.asc"
#
 Activate 60-Day Cloudera Enterprise Trial
enableEnterpriseTrial: true
```

For more information about Cloudera Manager licenses, see <u>Managing Licenses</u> in the Cloudera Manager documentation.

## **Deployment Template Configuration**

This section shows the structure of the Cloudera Manager deployment configuration settings in both the configuration file and the API.

### Configuration File

Using the configuration file, the configs section in the deployment template has the following structure:

```
cloudera-manager {
   configs {
     # CLOUDERA_MANAGER corresponds to the Cloudera Manager Server configuration options
      CLOUDERA_MANAGER {
         enable_api_debug: false
     # CLOUDERA_MANAGEMENT_SERVICE corresponds to the Service-Wide configuration options
      CLOUDERA_MANAGEMENT_SERVICE {
         enable_alerts : false
         enable_config_alerts : false
      ACTIVITYMONITOR { ... }
      REPORTSMANAGER { ... }
      NAVIGATOR { ... }
      # Added in Cloudera Manager 5.2+
      NAVIGATORMETASERVER { ... }
      # Configuration properties for all hosts
      HOSTS { ... }
   }
}
```

### API

Using the API, the configs section for deployment templates has the following structure:

```
"configs": {
        "CLOUDERA MANAGER": {
            "enable_api_debugi: "true"
        "CLOUDERA_MANAGEMENT_SERVICE": {
    "enable_alerts": "false"
   }
}
```

### Cluster Template Service-wide Configuration

This section shows the structure of the Cloudera Manager service-wide configuration settings in both the configuration file and the API.

### Configuration File

Using the configuration file, the configs section for service-wide configurations in the cluster template has the following structure:

```
cluster {
   configs
      HDFS
         dfs_block_size: 1342177280
      MAPREDUCE {
         mapred_system_dir: /user/home
         mr_user_to_impersonate: mapred1
```

```
}
}
...
```

### API

Using the API, the service-wide configurations block in the ClusterTemplate is labeled servicesConfigs, and has the following structure:

```
{
   "servicesConfigs": {
     "HDFS": {
        "dfs_block_size": 1342177280
     },
     "MAPREDUCE": {
        "mapred_system_dir": "/user/home",
        "mr_user_to_impersonate": "mapred1"
     }
}
```

## **Cluster Template Roletype Configurations**

This section shows the structure of the Cloudera Manager roletype configuration settings in both the configuration file and the API.

## **Configuration File**

Using the configuration file, roletype configurations in the cluster template are specified per instance group:

## API

Using the API, roletype configurations in the cluster template are specified per instance group:

# Ports Used by Cloudera Director

Cloudera Director needs to communicate with each of the nodes in the clusters that it manages. The simplest way to achieve this, if your organization's security policies allow it, is to enable all network traffic between Cloudera Director, cluster instances, and the Cloudera Manager node using any protocol on any port. You can do this in AWS by creating a security group for your VPC that allows traffic between its members and assigning this security group to Cloudera Director, Cloudera Manager, and all cluster instances. With this approach, you do not have to specify each port that is required by Cloudera Manager.

Туре	Protocol	Port Range	Source
ALL Traffic	ALL	ALL	security_group_id
SSH (22)	TCP (6)	22	0.0.0.0/0

In a restricted network environment, you may want to enable minimal network traffic between instances and keep open ports to a minimum.

- · Minimally, open port 22 for traffic to allow SSH access to the Cloudera Director server. If using SSH tunneling, the other Cloudera Director ports below are not required.
- Minimally, the Cloudera Director server needs SSH (port 22) access to every node in the cluster.
- Open outbound port 123 so that the Cloudera Manager and cluster nodes can access an NTP time server.
- Optionally, open port 7189 on the Cloudera Director server to enable access to the Cloudera Director web UI. Optionally, you can configure Cloudera Director to use HTTPS. You can configure a non-default port for the Cloudera Director web UI by adding the server . port property to the server application . properties file and specifying the desired port number. To enable HTTPS, configure the server.ssl.\* settings in the SSL section of the application.properties file.
- · Optionally, open port 7180 on the Cloudera Manager instances so that the Cloudera Director server can use port 7180 to interact with the Cloudera Manager API. (Otherwise, Cloudera Director will use SSH tunnels on port 22 to communicate with Cloudera Manager.)
- The Cloudera Director server needs access to outbound ports 80 and 443 to retrieve packages for initial installation, metering access, and for API access to the AWS, Azure, and Google APIs. Refer to AWS, Azure, and Google documentation for the exact domains.

For information on ports used by Cloudera Manager and CDH, see Ports in the Cloudera Manager documentation.

The following table summarizes the Cloudera Director port requirements described above:

Service	Role	Purpose	Default Port	Protocol	Required?
Cloudera Director Cloudera Director server	Cloudera Director web UI and API	7189 (configurable)	НТТР	No (SSH tunnel can be used instead)	
		Web UI and API	configurable	HTTPS	No (SSH tunnel can be used instead)
Clusters managed by Cloudera Cloudera Director Manager node	Cloudera Manager API	7180	НТТР	No (SSH tunnel can be used instead)	
		NTP	123 (outbound)	UDP	Yes
		Node installation	22	SSH	Yes

Service	Role	Purpose	Default Port	Protocol	Required?
Cluster	NTP	123 (outbound)	UDP	Yes	
	nodes	Node installation	22	SSH	Yes
archive.cloudera.com,		Software download/metering	80 (outbound)	НТТР	Yes*
metering.cloudera.com, AWS, Azure, and Google REST APIs, etc.	Director server and the Cloudera Manager node		443 (outbound)	HTTPS	Yes*

<sup>\*</sup>You can restrict access to archive.cloudera.com and metering.cloudera.com if you have an internal parcel repository and Cloudera Manager repository, and are not using usage-based billing (which requires metering), but your instances still require access to your cloud provider's REST APIs through HTTP or HTTPS.

# SSH Keys in Cloudera Director

# The Role of Keys in SSH

SSH is a protocol for communicating over an encrypted channel between computers. A common use of SSH is to connect to a remote computer in order to establish a shell process, within which commands may be issued. The SSH client logs in to the SSH server and receives a shell prompt. The client can issue shell commands, and then terminate the connection or log out when finished.

SSH uses the same kind of strong encryption that is used by TLS and SSL for encrypted web traffic. An observer should not be able to determine the contents of the network traffic between the client and the server. Through encryption, SSH provides confidentiality of communications.

When establishing an SSH connection for shell use, a client needs to authenticate to a server. Authentication can be performed in a few ways. One common way is through a username and password pair. While this is a well understood and widely supported means of authentication, it is vulnerable to the use of weak passwords.

A better option is to use a key pair. Like key pairs in TLS and SSL, an SSH key pair is composed of a private key and a corresponding public key. When the server is configured with the public key, the client can authenticate using the private key. Due to the way that the authentication mechanism works, the private key does not need to be passed over the network. Also, a private key is much larger, and much harder to guess, than a password. For these reasons, SSH key authentication is almost always preferred over password authentication.

### Use of SSH Keys in Cloud Providers

When a cloud provider creates a new instance, and you want to be able to connect to it over SSH, you must somehow inform the provider about the public key for authentication. The cloud provider is responsible for installing the public key in the correct location for it to work for authenticating with the corresponding private key.

The way that you tell a cloud provider about a key pair varies. For example, in AWS, you set up an EC2 key pair, which has an associated name. You can either have AWS generate the key pair and send you the data, or generate the key pair yourself and only upload the public key. No matter the provider, when you create an instance, you include information about the key pair.

Generally, the cloud provider copies the public key into the authorized\_keys file in the standard login account for the instance. This is enough to configure the instance's SSH server to allow authentication to that account with the corresponding private key. To use it on the command line:

ssh -i /path/to/private\_key.pem username@instance\_ip\_address

## Cloudera Director's Use of SSH Keys

Cloudera Director uses SSH to issue commands to instances that it launches and configures as part of bootstrapping deployments and clusters. Therefore, Cloudera Director requires the private key used to authenticate to the standard login account of each instance that it launches. It is insufficient for it to only be supplied the public key or an identifier for the private key material; only the private key itself is sufficient for authentication to succeed.

When you create a new environment in Cloudera Director, you supply the default username for a standard login account and the default SSH private key for authentication to that account. Every instance that Cloudera Director launches under the environment is accessed, by default, using the username and private key. An instance template, which specifies instance features like size and backing image, may override the username.

The private key must be provided to Cloudera Director in unencrypted form. However, Cloudera Director encrypts its own database where it stores private keys.

## Good Practices for SSH Key Management with Cloudera Director

- Use large key sizes. When creating an RSA key pair, use a key length of at least 2048 bits.
- Protect private keys by keeping them off the network. A cloud provider only requires the public key from an SSH key pair to launch instances you can authenticate to. The corresponding private key does not need to leave the computer where it was generated. Accordingly, for better security, instead of having AWS generate your key pair, generate it locally and upload only the public key.
- Change the Cloudera Director database encryption password. Cloudera Director ships with encryption of its own database enabled, but with a default encryption password. Follow the instructions for changing the encryption password in Starting with Encryption to avoid easy decryption if the database is compromised.
- Do not use personal SSH key pairs for Cloudera Manager and cluster instances. Instead, generate dedicated "service" SSH key pairs that are only for use by instances launched by Cloudera Director. This allows the lifecycle of personal and service key pairs to be managed separately. Also, service key pairs may then be shared without compromising any individual user's key pairs.
- Install additional SSH public keys on instances with bootstrap scripts. To permit wider authentication to instances, use a bootstrap script to append approved public keys to the authorized\_keys file for the standard login accounts, as an alternative to sharing the private key of the "primary" SSH key pair installed by the cloud provider.

# Creating AWS Identity and Access Management (IAM) Policies

In AWS, IAM files are used to create policies that control access to resources in a VPC. IAM roles allow EC2 instances to make API requests without the need to use or distribute AWS credentials (accessKey and secretAccessKey).

For more information about IAM, see the following topics in the AWS documentation:

- For an introduction to IAM, see AWS Identity and Access Management User Guide.
- For instructions on how to create an IAM role, see <u>Creating a Role to Delegate Permissions to an AWS Service</u>.
- For information on using IAM policies to manage access to Amazon RDS resources, see <u>Using Identity-Based Policies</u> (IAM Policies) for Amazon RDS.
- For information on constructing Amazon Resource Names (ARNs) for Amazon RDS resources, see Working with Amazon Resource Names (ARNs) in Amazon RDS.

Use the AWS Policy Generator to create the IAM file, keeping in mind the following requirements:

- For EC2, Cloudera Director requires permissions for the following methods:
  - CreateTags
  - DescribeAvailabilityZones
  - DescribeImages
  - DescribeInstanceStatus
  - DescribeInstances
  - DescribeKeyPairs
  - DescribePlacementGroups

- DescribeRegions
- DescribeSecurityGroups
- DescribeNetworkAcls
- DescribeSubnets
- DescribeInstanceAttribute
- RunInstances
- TerminateInstances
- To use SSH host key retrieval type with the PROVIDER option, the following additional EC2 permission is required:
  - GetConsoleOutput

For more information, see <u>SSH Host Key Retrieval and Verification</u>.

- To use EBS volumes, the following additional EC2 permissions are required:
  - CreateVolume
  - DescribeVolumes
  - AttachVolume
  - DeleteVolume
  - ModifyInstanceAttribute
- To use spot instances, the following additional EC2 permissions are required:
  - RequestSpotInstances
  - CancelSpotInstanceRequests
  - DescribeSpotInstanceRequests
- When working with encrypted EBS volumes (including AMIs with encrypted volumes) that use a custom key stored in KMS, Cloudera Director also requires the following KMS permissions:
  - DescribeKey
  - CreateGrant
  - ReEncrypt
  - GenerateDataKey
- To use the importKeyPairlfMissing property, Cloudera Director requires the following EC2 permission:
  - ImportKeyPair
- To validate the templates used for EC2 instance creation, Cloudera Director requires permissions for the following IAM methods:
  - GetInstanceProfile
  - PassRole
- To create RDS database servers for persistence on demand, Cloudera Director requires permissions for the following methods:
  - CreateDBInstance
  - DeleteDBInstance
  - DescribeDBInstances
  - DescribeDBEngineVersions
  - DescribeDBSubnetGroups

### Example IAM Policy

The following example IAM policy shows the format to use with Cloudera Director. Your Amazon Resource Name (ARN) will be different. For more information on ARNs, see Amazon Resource Names (ARNs) and AWS Service Namespaces in the AWS documentation.

```
"Version": "2012-10-17",
    "Statement": [
            "Sid": "directorEc2",
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
                "ec2:DescribeAvailabilityZones",
                "ec2:DescribeImages",
                "ec2:DescribeInstanceStatus",
                "ec2:DescribeInstances",
                "ec2:DescribeKeyPairs"
                "ec2:DescribePlacementGroups",
                "ec2:DescribeRegions",
                "ec2:DescribeSecurityGroups",
                "ec2:DescribeNetworkAcls",
                "ec2:DescribeSubnets",
                "ec2:DescribeInstanceAttribute",
                "ec2:RunInstances",
                "ec2:TerminateInstances",
                "ec2:CreateVolume",
                "ec2:DescribeVolumes"
                "ec2:AttachVolume",
                "ec2:DeleteVolume",
                "ec2:ModifyInstanceAttribute",
                "ec2:ImportKeyPair",
                "ec2:RequestSpotInstances",
                "ec2:CancelSpotInstanceRequests",
                "ec2:DescribeSpotInstanceRequests",
                "ec2:GetConsoleOutput"
            "Resource": "*"
            "Sid": "directorKms",
            "Effect": "Allow",
            "Action": [
                "kms:DescribeKey",
                "kms:CreateGrant",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*"
            1.
            "Resource": "*"
            "Sid": "directorIam",
            "Effect": "Allow",
            "Action": [
                "iam:GetInstanceProfile",
                "iam:PassRole"
            "Resource": "*"
            "Sid": "directorRds",
            "Effect": "Allow",
            "Action": [

                "rds:DeleteDBInstance",
                "rds:DescribeDBInstances"
                "rds:DescribeDBEngineVersions"
            "Resource": "*"
        }
    ]
}
```

# Using Custom Repositories with Cloudera Manager and CDH

You can create a custom repository to use when deploying Cloudera Manager and CDH, for example, if your organization restricts internet access to the Cloudera repositories, or if you wish to use custom AMIs preloaded with Cloudera Manager packages and CDH parcels.

## Creating a Custom Repository

See Creating and Using a Package Repository for Cloudera Manager in the Cloudera Manager documentation for instructions and a link for downloading the Cloudera Manager repository for various operating systems. Following these instructions will ensure that your repository is created with the required directory structure. Be sure to choose an operating system that is supported by Cloudera Director.

## Creating a Cloudera Manager and CDH AMI

For clusters running on AWS EC2 instances, you can reduce cluster bootstrap times by preloading the AMI with Cloudera Manager packages and CDH parcel files. For information on creating AMIs preloaded with Cloudera Manager packages and CDH parcels for use by Cloudera Director see the README.md file on the Cloudera GitHub site.

Note: If you are using an AMI that already has Cloudera Manager or CDH pre-loaded on it, you must override the repository in Cloudera Director by specifying a custom repository URL in the custom repository field. The version you specify in this URL override must match what is on your AMI, down to the three digits of the maintenance release. For example, if you have CDH 5.5.1 on the AMI, the repository you specify should be /5.5.1 and not /5.5 or /5.

# Cloudera Manager Health Information

The following Cloudera Manager health information is available through Cloudera Director server:

- Host health
- · Service health
- · Cluster health

The health value is displayed in the Status column for each entity, when health information is available. Possible health values are:

- Disabled Health collection has been disabled on Cloudera Manager.
- Not Available Cloudera Director does not currently have health information, or a health has "expired."
- Bad Cloudera Manager reports the health as bad.
- Concerning Cloudera Manager reports the health as concerning.
- Good Cloudera Manager reports the health as good.

You can configure the health cache with the following settings in the application.properties file:

- lp.cache.health.pollingRateInMilliseconds How often the Cloudera Director server polls Cloudera Manager for health information. The default value is 30,000 ms (30 seconds). To disable health collection, set lp.cache.health.pollingRateInMilliseconds to 0.
- lp.cache.health.numberOfHealthCacheExecutorThreads The number of threads used to simultaneously request health information from Cloudera Manager. the default value is 5.
- lp.cache.health.expirationMultiplier Used to determine if a health value is stale. If the health value has not been updated in pollingRateInMilliseconds \* expirationMultiplier milliseconds, then the health value is considered stale and is reported to the web UI as NOT AVAILABLE. Using the default settings, for example, if health has not been reported in 2 \* 30,000 milliseconds = 60 seconds, it becomes stale. The default value is 2.

Note: Cloudera Manager health is collected by Cloudera Director server only, not by Cloudera Director

# Opening Cloudera Manager

After deploying a cluster, you can manage it using Cloudera Manager:

- 1. Log in to Cloudera Director. For example, http://example.com:7189.
  - Cloudera Director opens with a list of clusters.
- 2. Locate the cluster to manage and click its Cloudera Manager. The link is available when Cloudera Manager is ready.
- 3. On the Cloudera Manager Login page, enter your credentials and click Login. Cloudera Manager opens.

# Diagnostic Data Collection

Cloudera Manager log files provide important information for Cloudera Support to use in analyzing problems or unexpected behavior with Cloudera Manager deployments or CDH clusters. Cloudera Director triggers the collection of diagnostic data for deployments and clusters it manages. This helps prevent situations where a failed cluster has been terminated but Cloudera Support has no diagnostic data or log files to help identify the cause of the failure. If you have a Cloudera Enterprise or Cloudera Enterprise Trial license, diagnostic data is collected and sent to Cloudera Support automatically on cluster bootstrap or update failure. By default, diagnostic data is also downloaded to the Cloudera Director instance.

If Cloudera Manager cannot collect diagnostic data, no information is sent to Cloudera Support, and the Cloudera Manager service logs are downloaded to Cloudera Director instead of the diagnostic data. The logs contain less information than the diagnostic data, but can still be useful to Cloudera Support for analyzing deployment and cluster behavior.

Note: If you are using a Cloudera Express license instead of a Cloudera Enterprise license, the Collect Diagnostic Data action results in the downloading of Cloudera Manager service logs to Cloudera Director. These logs are not uploaded to Cloudera Support.

You can initiate diagnostic data collection manually through the Cloudera Director web UI or API. You can collect diagnostic data for an entire Cloudera Manager deployment or for a specific CDH cluster.

For more information on how diagnostic data collection works in Cloudera Manager, see the Cloudera Manager documentation page Sending Usage and Diagnostic Data to Cloudera.

### Manual Collection of Diagnostic Data

You can manually trigger the collection of diagnostic data using either the Cloudera Director web UI or the Cloudera Director API.

### Using the Web UI

To trigger diagnostic data collection, perform the following steps:

- 1. Go to the Cloudera Director web UI page for the deployment or cluster.
- 2. Click the down arrow on the dropdown list to the right of the deployment or cluster name.
- 3. In the dropdown list, click Collect Diagnostic Data.

Cloudera Director makes an API call to the Cloudera Manager API collectDiagnosticData. If successful, Cloudera Manager sends the diagnostic data to Cloudera Support and, if the download diagnostic data property is set to true

in the Cloudera Director application.properties file, also downloads a zip file containing the diagnostic data for the deployment or cluster to the Cloudera Director EC2 instance. If diagnostic data collection is unsuccessful, and the download diagnostic data property is set to true, Cloudera Manager downloads the Cloudera Manager service logs to Cloudera Director.

### Manually Triggering Collection of Diagnostic Data at Cluster Termination

When you terminate a Cloudera Manager deployment or CDH cluster in the web UI, the screen for confirming the termination includes a button that triggers collection of diagnostic data:

Note: Diagnostic data collection is also triggered before termination when you invoke the terminate-remote command with the Cloudera Director CLI. There is no separate CLI command to trigger collection of diagnostic data, so you must use the web UI or API to trigger diagnostic data collection without terminating the deployment or cluster.

### Using the API

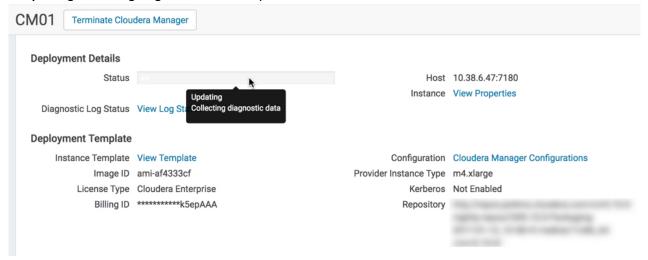

To manually trigger collection of diagnostic data for Cloudera Manager deployments, use the API at http://cloudera\_director\_ip:port\_number/api-console/index.html#!/deployments/collectDiagnosticData.

To manually trigger collection of diagnostic data for CDH clusters, use the API at

http://cloudera\_director\_ip:port\_number/api-console/index.html#!/clusters/collectDiagnosticData.

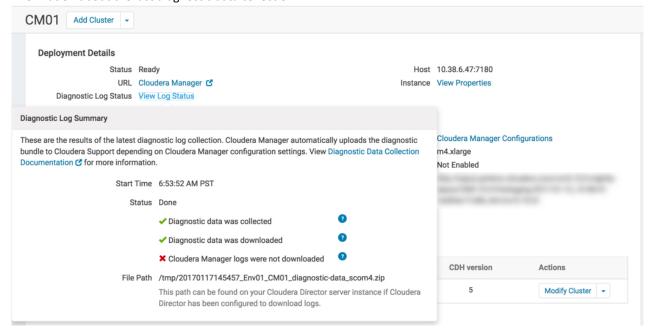

### Status for Data Collection

While diagnostic data collection is in progress, the status of the deployment or cluster changes from its current state to **Updating: Collecting diagnostic data** when you mouse-over the **Status** bar:

The cluster status is not actually updated; the updating message is displayed simply to inform that diagnostic data collection is in progress. Because diagnostic data collection does not change the status of the cluster, when the data collection is complete, the deployment or cluster status message reverts to what it was before diagnostic data collection began.

If you click View Log Status on the deployment or cluster screen, the Diagnostic Log Summary is displayed, showing information about the last diagnostic data collection:

If diagnostic data has never been collected for the deployment or cluster, the Diagnostic Log Status value is Not Collected and there is no link to open the Diagnostic Log Status screen.

### Configuring Diagnostic Data Collection

By default, Cloudera Manager sends diagnostic data to Cloudera Support and to Cloudera Director. You can configure diagnostic data collection on Cloudera Manager and Cloudera Director using the procedures described in this section.

### Configuring Upload of Diagnostic Data to Cloudera Support

The Cloudera Manager server property that determines whether diagnostic data is automatically sent to Cloudera Support has the display name Send Diagnostic Data to Cloudera Automatically and the API name phone home. The default value for this property is true. To disable diagnostic data collection in Cloudera Manager, set this property to false. Set the property in Cloudera Manager by following these steps:

- 1. In Cloudera Manager, click Administration > Settings.
- 2. In the list of Filters in the lefthand pane, click Support.
- 3. Click the checkbox for the property Send Diagnostic Data to Cloudera Automatically to toggle the setting between true and false.

For more information on the phone\_home property, see the table in the Support section of Cloudera Manager Server Properties.

### Configuring Download of Diagnostic Data to Cloudera Director

Several Cloudera Director server configuration properties affect the way diagnostic data is handled. You can set these properties in the application.properties file located at /etc/cloudera-director-server/ on the Cloudera Director instance, or at the command line.

- lp.debug.collectDiagnosticDataOnFailure: Determines whether automatic collection of diagnostic data occurs for cluster bootstrap or update failures. The default value is true.
- lp.debug.downloadDiagnosticData: Determines whether diagnostic data is downloaded to the Cloudera Director instance. The default value is true.

- lp.remote.terminate.assumeYes: Determines whether Cloudera Director skips prompting the user to confirm termination when the terminate-remote command is invoked. If you set the property to true, termination proceeds even if diagnostic data collection has failed. The default setting is false.
- lp.debug.diagnosticDataDownloadDirectory: Sets a nondefault path for the download of diagnostic data for deployments and clusters. The default location is /tmp. The directory where diagnostic data has been downloaded appears in the File Path field in the Diagnostic Log Summary.
- lp.debug.createDiagnosticDataDownloadDirectory: Determines whether Cloudera Director creates the nondefault download directory specified in lp.debug.diagnosticDataDownloadDirectory if it does not exist. The default value is true.

For information about setting Cloudera Director properties by using the CLI or editing the application.properties file, see Setting Cloudera Director Properties on page 176.

# **User Management**

User roles control the actions a user can perform. There are currently two user roles:

- Admin For administrative access. Has full access to Cloudera Director functionality, and can perform the following actions:
  - Add environments, Cloudera Manager instances, and clusters
  - Delete environments
  - Terminate Cloudera Manager and cluster instances
  - Review environments, Cloudera Manager instances, and clusters
  - Grow and shrink clusters
  - Add and delete users
  - Change user roles
  - Change passwords, including own password
- Guest For read-only access.

On installation, the Cloudera Director server component includes one of each of the two kinds of user accounts:

- admin Default password: admin
- guest Default password: guest

Cloudera recommends that you change the passwords for these accounts after installing the server. User accounts can be created, deleted, enabled, or disabled. A disabled user account cannot log in or perform any Cloudera Director actions.

User account data is kept in the Cloudera Director database. You can define new user accounts for Cloudera Director with either the server web UI or the API.

Note: Cloudera Manager has many more user roles that control access to Cloudera Manager features. For more information see <u>Cloudera Manager User Roles</u> in the Enterprise documentation.

### Managing Users with the Cloudera Director Web web UI

You can perform the following user management operations through the Cloudera Director Web web UI:

### **Create a User Account**

To create a new user account, perform the following steps:

- 1. On the Cloudera Director home screen, click the dropdown menu in the upper right and click Manage Users.
- 2. Click the Add User button.
- 3. Enter a username and password for the new user, and select a role (Admin or Guest).
- 4. Click Add User.

### **Disable a User Account**

To disable an existing user account, perform the following steps:

- 1. On the Cloudera Director home screen, click the dropdown menu in the upper right and click Manage Users.
- 2. Click the checkbox next to the user account you want to disable.
- 3. Click the dropdown menu for the user account in the Actions column and click Disable User.
- **4.** Confirm that user you have disabled now appears as unavailable on the Manage Users screen.

You can use the same procedure to enable a user account that is currently disabled. The Actions dropdown list displays the item **Enable User** for a user account that is currently disabled.

### **Change User Account Passwords**

Users with the admin role can change any user's password. Guest users can change only their own password.

To change your own password, perform the following steps:

- 1. On the Cloudera Director home screen, click the dropdown menu in the upper right and click Change password.
- 2. Enter your current password, a new password, and the new password again to confirm.
- 3. Click Save changes.

To change another user's password, perform the following steps (using the required Admin role):

- 1. On the Cloudera Director home screen, click the dropdown menu in the upper right and click Manage Users.
- 2. Click the checkbox next to the user whose password you want to change.
- 3. Click the dropdown menu for the user account in the Actions column and click Change password.
- **4.** Enter a new password and enter the password again to confirm.
- 5. Click Save changes.

### Change a User's Role

An Admin user can change another user's role by performing the following steps:

- 1. On the Cloudera Director home screen, click the dropdown menu in the upper right and click Manage Users.
- 2. Click the checkbox next to the user whose role you want to change.
- 3. Click the dropdown menu for the user in the Actions column and click Change role.
- **4.** Select the new role in the **Role** dropdown menu.
- 5. Click Save changes.

### **Delete a User Account**

An Admin user can delete a user account by performing the following steps:

- 1. On the Cloudera Director home screen, click the dropdown menu in the upper right and click Manage Users.
- 2. Click the checkbox next to the user account you want to delete.
- 3. Click the dropdown menu for the user account in the Actions column and click Delete.
- 4. Click Delete to confirm.

### Managing Users with the Cloudera Director API

Cloudera Director server has a REST service endpoint for user management, at director-server-hostname:7189/api/v9/users. You can perform the following user-management operations with the Cloudera Director API. They all use JSON for input data and response data.

REST method	Description
GET /api/v9/users	Lists all usernames.
POST /api/v9/users	Creates a new user account (Admin role required).
GET /api/v9/users/current	Gets account information on the currently logged-in user.
GET /api/v9/users/{username}	Gets account information on a user.

REST method	Description
PUT /api/v9/users/{username}	Changes account information on a user.
DELETE /api/v9/users/{username}	Deletes an account (Admin role required)
PUT /api/v9/users/{username}/password	Changes an account password for Guests; old password required, and Guests can only change their own account.

For information on managing users with the Cloudera Director API, see the server API documentation at director-server-hostname:7189/api-console. Expand the section labeled users.

# Using Cloudera Director Server to Manage Cluster Instances

This section includes topics on managing CDH cluster instances:

# The Cloudera Director Configuration File

The Cloudera Director configuration file is used to launch a cluster through Cloudera Director client with the bootstrap command, or through the Cloudera Director server with the bootstrap-remote command.

For information on the bootstrap and bootstrap-remote commands, see Commands on page 13. The configuration file follows the HOCON format. For information on HOCON, see the documentation on GitHub at HOCON (Human-Optimized Config Object Notation).

### Location of Sample Configuration Files

Sample configuration files are found either in /usr/lib64/cloudera-director/client or /usr/lib/cloudera-director/client, depending on the operating system you are using. Copy the sample files to your home directory before editing them.

## Customizing the Configuration File

Copy the sample files to your home directory before editing them. Rename the cloud provider.simple.conf or cloud\_provider.reference.conf file to your\_filename.conf.

- For simple cluster configuration, use *cloud-provider*.simple.conf.
- For advanced cluster configuration, use *cloud provider*.reference.conf.

**Important:** The configuration file must use the .conf file extension.

Open your copy of the configuration with a text editor to customize the configuration settings.

The cloud\_provider.reference.conf version of the configuration file includes advanced settings that are documented in comments within the file itself. Details on the specific settings in the file are not duplicated in this document.

## Valid Role Types for Use in Configuration Files

For a list of valid roles for Cloudera Manager and CDH services that you can use in a Cloudera Director configuration file, see the Cloudera Manager API page on Available Role Types.

### Using the API to Import a Configuration File

Beginning with release 2.0 of Cloudera Director, you can import the contents of a configuration file into Cloudera Director with the API using the /api/<api\_version>/import endpoint. For example:

/api/v10/import?clusterName=someClusterName&deploymentName=someDeploymentName&environmentName=someEnvironmentName

In this way, you can POST the contents of a configuration file to Cloudera Director without using the Cloudera Director CLI. The values clusterName, deploymentName, and environmentName are all optional. If they are present, they override the values in the configuration file.

# Submitting a Cluster Configuration File

In Cloudera Director, you can deploy clusters in two ways:

- Through the Cloudera Director server web UI.
- Through the Cloudera Director client, which you can use to send a configuration file that the server uses for cluster deployment. The configuration file provides advanced options not available in the server web UI.

This section describes the second of these ways, using the Cloudera Director client to submit a configuration file. The configuration file will be applied to the cluster and managed by the Cloudera Director server.

When you submit a cluster configuration from a Cloudera Director client to the Cloudera Director server, all communications are transmitted in the clear (including the AWS credentials). If the client and server communicate over the Internet, use a VPN for security.

Note: If you create tags in the configuration file for AWS or Google Cloud Platform instance metadata or for service or role configurations, special characters, such as periods and colons, must be enclosed in double quotes. This includes some characters required by the HOCON format. For example, a tag value that would require quoting is "company:department:team". See the AWS and Google Cloud Platform documentation for information about which special characters are supported on these cloud platforms in instance metadata tags.

To submit a cluster configuration file to the Cloudera Director server, follow these steps:

- 1. Create a configuration file. See Provisioning a Cluster on AWS on page 220.
- 2. Install the latest version of the Cloudera Director client from the Cloudera Director Download Page.
- **3.** Enter the following command:

```
cloudera-director bootstrap-remote myconfig.conf --lp.remote.username=admin
--lp.remote.password=admin --lp.remote.hostAndPort=host:port
```

myconfig.conf is the name of your configuration file, admin is the default value for both the username and password for the Admin account (enter your actual values), host is the hostname or IP address of the instance on which Cloudera Director server is running, and port is the port on which it is listening. The default port for Cloudera Director is 7189.

Both the Cloudera Director client (in the terminal where the bootstrap-remote command was issued) and the Cloudera Director server web UI display the status throughout the deployment process.

# Deploying Clusters in an Existing Environment

If you already configured an environment, you can easily deploy a new cluster:

- 1. Log in to Cloudera Director. For example, http://example.com:7189.
- 2. Click Add Cluster, and then select an environment from the Environment list box. .
- 3. Select a Cloudera Manager from the Cloudera Manager list box.
- 4. To clone an existing cluster, select Clone from existing and select a cluster. To specify cluster settings, select Create from scratch.
- **5.** Enter a name for the cluster in the **Cluster name** field.
- 6. Enter the version of CDH to deploy in the Version field or leave the default value. By default, the version of CDH that will be installed depends on the version of Cloudera Director you are using:
  - If you are using Cloudera Director 2.0, the latest released version of Cloudera Manager/CDH 5.5 will be installed by default.
  - If you are using Cloudera Director 2.1, the latest released version of Cloudera Manager/CDH 5.7 will be installed by default.

To install an earlier or later version of CDH than the default version, perform the following steps:

- a. Enter the desired CDH version in the Version field of the Products section. For example, for CDH 5.4.8 enter 5.4.8.
- **b.** Scroll down to **Configurations (optional)** and expand the section.
- c. Click Override default parcel repositories.
- d. Enter the repository parcel URL for the version of CDH you want to install. Parcel URLs for versions of CDH 5 take the form https://archive.cloudera.com/cdh5/parcels/, followed by the major, minor, and (if applicable) dot release number. For example, the URL for CDH 5.4.8 is https://archive.cloudera.com/cdh5/parcels/5.4.8.

**Note:** The CDH minor version must not be greater than the Cloudera Manager minor version. For example, CDH 5.7 will not work with Cloudera Manager 5.5, but CDH 5.7 (or lower) will work with Cloudera Manager 5.7.

- **7.** Select the type of cluster to deploy from **Services**.
- 8. Select the numbers of masters, workers, and gateways to deploy. Then, select an instance template for each or create one or more new templates.
- 9. When you are finished, click **Continue**. When prompted for confirmation, click **OK** to confirm.

Cloudera Director begins deploying the cluster.

Note: If your root disk drive is larger than all the other drives on the machine, Cloudera Manager automatically installs HDFS on the root drive.

# **Using Spot Instances**

To help you manage your cloud resource costs, Cloudera supports AWS Spot instances. Spot instances are Amazon EC2 instances that you can bid on. They run just like On-Demand instances, except that they are not provisioned until the instance price falls below your bid price. Amazon will terminate the instances when the instance price exceeds your bid price. Spot instances allow you to add capacity to your clusters at a low price.

Cloudera Director supports Spot instances for worker roles on the following services:

- YARN
- · Hive on Spark
- Hive on MapReduce
- Spark

For all other components and for master roles, Cloudera recommends using on-demand instances.

Note: Amazon EC2 does not currently support Spot instances on Red Hat Enterprise Linux (RHEL). Spot instances must be run on supported Centos AMIs.

Although Spot instances are supported with Cloudera Director 2.0 and higher, Cloudera recommends using Cloudera Director 2.5 and higher together with Cloudera Manager and CDH 5.12 and higher for Spot instances. Beginning with these versions, Cloudera has improved cluster resiliency to support Spot instances better. Now, if Amazon terminates a Spot instance during a bootstrap or update operation, Cloudera Director will shrink the terminated instance out of the cluster, as long as the affected instance group still meets the minimum count requirement. For this reason, Cloudera recommends specifying a minimum count of zero for instance groups that use Spot instances. (See Best Practices for <u>Using Spot Instances</u> on page 206 below.)

### Using Cloudera Director Server to Manage Cluster Instances

Note: With versions of Cloudera Director lower than 2.5 and versions of Cloudera Manager and CDH lower than 5.12, a cluster will fail if Amazon terminates a Spot instance during a bootstrap or update operation. If a bootstrap operation fails, it cannot be recovered, and a new cluster must be launched in its place. If an update operation fails, it may be possible to recover cluster functionality, but only with the assistance of Cloudera Support.

Note: Because Spot instances are terminated by AWS if the Spot price you bid becomes lower than the current Spot price, you should not use Spot instances for master nodes or for data storage. Use Spot instances only for instances where the loss of the instance can be tolerated, such as compute nodes or other worker nodes.

For more information about using Spot instances, see the Amazon EC2 documentation. For help with bidding on Spot instances, see the Spot Bid Advisor.

## Planning for Spot Instances

It is normal for Spot instances on a cluster to disappear over time. However, Cloudera Manager does not see that these instances are terminated. If you use Cloudera Manager to restart a cluster that contains a Spot instance group, and the Spot instances have terminated, the restart fails. If you are modifying any group in the cluster that has lost Spot instances, do not select the **Restart** checkbox.

If your bid price is so low that you do not obtain an instance when the group is created, you will have 0 instances in your group. If this happens, you can:

- Delete the entire group.
- Add more instances to the group.
- Delete unprovisioned instances from the group (only as part of adding more instances to the group).
- · Retry (repair) existing instances.

You cannot do the following:

• Change the bid price for spot instances.

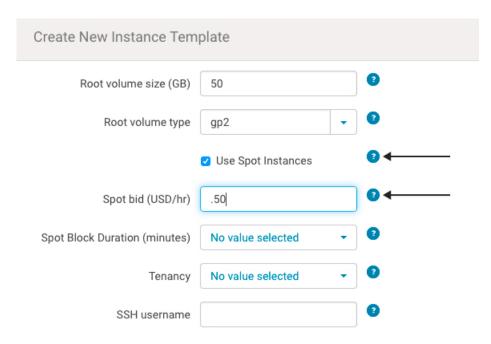

**Note:** Although you cannot change the bid price for a spot instance, you can work around this restriction by adding a new, identical virtual instance group with the desired bid price.

Delete all instances without adding more, due to the minimum instance count requirement.

The bid price for Spot instances is set in an instance template. This template is associated with a group. Although you can modify the group, you cannot change the bid price. Therefore, if you set the bid price too low for successful provisioning, you must delete the group where that price is set and create a new group with the higher bid price. You must also delete the current group and create a new one if you want to drop the bid price.

### Specifying Spot Instances

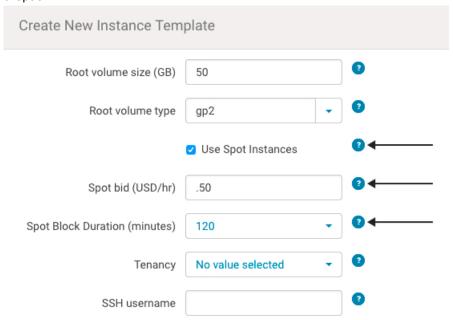

To specify Spot instances, create a new instance template and use this template for your instance group. In the Advanced Options section of the Create New Instance Template wizard, check the Use Spot Instances checkbox and enter a value in the Spot bid field.

## Spot Blocks: Specifying a Duration for Spot Instances

The AWS Spot block feature enables you to specify a fixed duration ranging from one to six hours for Spot instances. Spot instances with a predefined duration use a fixed hourly price that remains in effect for the Spot instance while it runs. The price for instances with a Spot block will not be as low as that for ordinary Spot instances, but will be lower than that of on-demand instances, and Spot block instances are guaranteed to run for the specified duration, after which they are terminated.

To configure an instance template for Spot block instances, check the Use Spot Instances checkbox, enter a value in the Spot bid field, and choose a value from one to six hours (in intervals of 60 minutes) in the Spot Block Duration dropdown.

See Specifying a Duration for Your Spot Instances in the AWS documentation for more information about Spot blocks.

### Best Practices for Using Spot Instances

- Use a Spot instance worker group in conjunction with an On-Demand worker group. This ensures that the cluster can redo computational tasks run on Spot instances that could be terminated before the tasks are finished.
- Use Spot instances only in contexts where the loss of the instance can be tolerated, as in a worker group. Do not use Spot instances for master nodes or for data storage.
- Use a minimum count of 0 for Spot instance groups. If you use a number above 0, the cluster will likely enter a failed state. If the cluster fails, contact Cloudera support for help.

Additional best practices for using spot instances can be found in <u>Spot Instance Interruptions</u> in the AWS documentation.

# Using Products outside CDH with Cloudera Director

Products packaged in parcels separate from the CDH parcel may be included in clusters that are bootstrapped with Cloudera Director. Create a configuration file that includes the desired products (see <u>The Cloudera Director Configuration</u> <u>File</u> on page 201 for more information), and then use the Cloudera Director CLI to bootstrap a cluster with the services.

## **Custom Service Descriptors**

A custom service descriptor (CSD) is a file that describes a product for use with Cloudera Manager. When a product is accompanied with a CSD, Cloudera Manager can support configuration, distribution, and monitoring of that product. See <u>CSD Overview</u> for an overview of CSDs.

Most products available via parcel are accompanied by a CSD. Starting in Director 2.4, you can point to CSDs that Cloudera Director should download and install into Cloudera Manager during the bootstrap process. Once a CSD is installed, its corresponding product distributed in a parcel can then be installed properly in clusters managed by Cloudera Manager.

To install a CSD into Cloudera Manager, provide a URL for it in the deployment template, in the csds section.

```
cloudera-manager {
    ...
    csds: [
        "https://archive.cloudera.com/spark2/csd/SPARK2_ON_YARN-2.0.0.cloudera2.jar",
        "https://archive.cloudera.com/kudu/csd/KUDU-5.10.0.jar",
    ]
}
```

During deployment bootstrap, Cloudera Director will download each CSD from its URL and install it into the correct location for Cloudera Manager to recognize it.

### **Custom CSD Installation Directory**

You may define a non-default location for CSD installation using the csd\_repo\_path Cloudera Manager server configuration property.

```
...
cloudera-manager {
...
configs {
csd_repo_path: /custom/path/to/csds
...
}
```

When this configuration property is specified in a deployment template, Cloudera Director installs CSD files into the custom location instead of the default location.

### CSD Support Before Cloudera Director 2.4

The ability to define CSDs for installation in deployment templates is a new feature for Cloudera Director 2.4. For earlier versions of Cloudera Director, use a different mechanism to install CSD files for Cloudera Manager. Here are some options:

- Use a deployment post-creation script to download CSDs to the newly allocated Cloudera Manager instance. See Deployment Post-creation Scripts for more information.
- Use an image for the Cloudera Manager instance which already includes CSDs.

### Installing CSDs after Deployment Bootstrap

You may install additional CSDs into Cloudera Manager after Cloudera Director has bootstrapped it. Cloudera Manager must be restarted for it to recognize the new CSDs. Future bootstraps of new clusters that use the updated Cloudera Manager installation may include the products corresponding to the CSDs, as if Cloudera Director itself had originally installed them.

### Using Kudu with CDH 5.12 or Earlier

For Kudu 1.4 and earlier with CDH 5.12 and earlier, the Kudu service is distributed in its own parcel and is not part of CDH. To add Kudu to a CDH 5.12 or earlier cluster, bootstrapped by Cloudera Director, perform the following steps.

- 1. List "KUDU" as a product in the cluster template, providing its version number.
- 2. Include the URL for a Kudu parcel repository in the list of parcel repositories for the cluster template. Be sure to also include the URL for the CDH parcel repository, even if it is the default repository that Cloudera Director uses when no parcel repositories are listed.
- **3.** Manually assign roles for Kudu, as well as other products, to instances in the cluster template.
- 4. Provide required Kudu configuration properties, such as the paths for the data and write-ahead log files.

```
. . .
cluster {
  products {
    CDH: 5.11.0,
    KUDU: 1.2.0
  parcelRepositories: ["https://archive.cloudera.com/cdh5/parcels/5.11.0/",
                        "https://archive.cloudera.com/kudu/parcels/5.11.0/"]
  services: [HDFS, YARN, KUDU]
  masters {
    count: 1
    instance: {
      type: m4.xlarge
      image: ami-12345678
    roles {
      HDFS: [NAMENODE, SECONDARYNAMENODE]
      YARN: [RESOURCEMANAGER, JOBHISTORY]
      KUDU: [KUDU_MASTER]
    configs {
      KUDU {
        KUDU_MASTER {
  fs_wal_dir: "/data0/kudu/masterwal"
           fs_data_dirs: "/data1/kudu/master"
    }
  workers {
    count: 3
    minCount: 3
    instance: {
```

### Using Cloudera Director Server to Manage Cluster Instances

```
type: m4.xlarge
      image: ami-12345678
    roles {
      HDFS: [DATANODE]
      YARN: [NODEMANAGER]
      KUDU: [KUDU_TSERVER]
    configs {
        KUDU_TSERVER {
   fs_wal_dir: "/data0/kudu/tabletwal"
           fs_data_dirs: "/data1/kudu/tablet"
      }
    }
  }
}
```

The Kudu configurations above are examples only. Check the Kudu documentation for the complete set of required configurations. Also note that valid paths for files depend on the file systems that are established in cluster instances, which depend on the underlying operating system images.

The CSD for Kudu is included with Cloudera Manager starting with version 5.11. If you are using that version or later of Cloudera Manager, you do not need to list the Kudu CSD in the csds section of the deployment template. Otherwise, do include the CSD.

```
cloudera-manager {
  # Kudu CSD is not included with Cloudera Manager 5.10
  csds: [
     "https://archive.cloudera.com/kudu/csd/KUDU-5.10.0.jar"
}
```

To learn more about using Kudu alongside CDH, see Installing Kudu in the Cloudera Enterprise documentation.

### Using Spark 2 with Cloudera Director

The Spark 2 service is distributed in its own parcel and is not part of CDH. (CDH includes Spark 1, but Spark 2 may be installed alongside Spark 1 in the same cluster.)

Note: Spark 2.2 requires JDK 8 and Python 2.7 or higher. For information on using Java 8 with Cloudera Director, see **Deploying a Java 8 Cluster**.

To add Spark 2 to a cluster bootstrapped by Cloudera Director, perform the following steps.

- 1. List "SPARK2" as a product in the cluster template, providing its version number.
- 2. Include the URL for a Spark 2 parcel repository in the list of parcel repositories for the cluster template. Be sure to also include the URL for the CDH parcel repository, even if it is the default repository that Cloudera Director uses when no parcel repositories are listed.
- 3. Manually assign roles for Spark 2, as well as other services, to instances in the cluster template.
- 4. Provide the URL for the corresponding Spark 2 CSD in the list of CSDs in the deployment template.

```
cloudera-manager {
  csds: [
     "https://archive.cloudera.com/spark2/csd/SPARK2_ON_YARN-2.0.0.cloudera2.jar"
```

```
"https://archive.cloudera.com/kudu/csd/KUDU-5.10.0.jar",
  ]
}
cluster {
  products {
    CDH: 5.11.0,
    SPARK2: 2.0.0.cloudera2
  parcelRepositories: ["https://archive.cloudera.com/cdh5/parcels/5.11.0/",
                        "https://archive.cloudera.com/spark2/parcels/2.0.0.cloudera2/"]
  services: [HDFS, YARN, SPARK2_ON_YARN]
  masters {
    count: 1
    instance: {
      type: m4.xlarge
      image: ami-12345678
    roles {
      HDFS: [NAMENODE, SECONDARYNAMENODE]
      YARN: [RESOURCEMANAGER, JOBHISTORY]
      SPARK2_ON_YARN: [SPARK2_YARN_HISTORY_SERVER]
  workers {
    count: 3
    minCount: 3
    instance: {
      type: m4.xlarge
      image: ami-12345678
    roles {
      HDFS: [DATANODE]
      YARN: [NODEMANAGER]
```

To learn more about using Spark 2 alongside CDH, see Cloudera Distribution of Apache Spark 2 Overview.

### Using Cloudera Data Science Workbench with Cloudera Director

With Cloudera Manager 5.13.1 and higher and Cloudera Director 2.6.0 and above on AWS, you can include Cloudera Data Science Workbench when installing CDH by using the Cloudera Director configuration file aws.cdsw.conf.

Note: Be sure to set the lp.normalization.mountAllUnmountedDisksRequired property to false in the Cloudera Director server's application.properties file and then restart Cloudera Director before you run the command to bootstrap a new cluster that includes Cloudera Data Science Workbench. For more information about using Cloudera Data Science Workbench with Cloudera Director, see Cloudera Director Support (AWS Only) in the Cloudera Data Science Workbench documentation.

## Using Third-Party Products with Cloudera Director

Some products created by Cloudera partners are packaged as separate parcels, with or without accompanying CSDs. These can be included in clusters bootstrapped by Cloudera Director.

### Required Information

The following information is needed to successfully include a third-party product in a Cloudera Director configuration file. If you cannot determine this information yourself, consult the partner documentation for the product.

### Using Cloudera Director Server to Manage Cluster Instances

- The URL for the directory containing the desired product parcel. This is the parcel repository URL that must be included in the Cloudera Director cluster template. Parcels for different operating systems may be co-located in one repository. It is necessary that this directory also contain a standard manifest.json file that is interpreted by Cloudera Manager to select the appropriate parcel for a cluster.
- The name of the product, which is usually the initial part of the parcel file name.
- The URL for the product's corresponding CSD, if one is provided. Some products do not require CSDs.
- The names of the services that comprise the product, and the roles that comprise each service. These are listed in the SDL file that is part of the CSD.
- Any required configuration properties for services or roles.

### Additions to a Cloudera Director Configuration File

To add a third-party product to a cluster bootstrapped by Cloudera Director, perform the following steps:

- 1. List the name of the parcel product in the cluster template, providing its version number.
- 2. Include the URL for the product's parcel repository in the list of parcel repositories for the cluster template. Be sure to also include the URL for the CDH parcel repository, even if it is the default repository that Cloudera Director uses when no parcel repositories are listed.
- **3.** Manually assign roles for each desired service in the product, as well as other services like those included in CDH, to instances in the cluster template.
- 4. Provide the URL for the corresponding product CSD, if provided, in the list of CSDs in the deployment template.
- **5.** Provide any required configuration properties for the third-party services or roles.

### Validation Warnings

Cloudera Director does not validate the services and roles that are part of a third-party product. It is normal for Cloudera Director to report validation warnings for them, for example, for a service named "EXTRA SERVICE":

```
* Unknown service type: EXTRA_SERVICE. Skipping role type validation.
```

These warnings are normal, and Cloudera Director will proceed with the bootstrap process. Check Cloudera Manager for details on any product installation or configuration errors.

### Missing manifest.json File

Cloudera Director may fail with a validation error if the parcel repository URL for a third-party product is missing a manifest file.

```
* Unsuccessful response from URL: http://archive.example.com/product/1.2.3/manifest.json, http code: 404
```

Verify that the correct parcel repository URL was provided in the cluster template; it should be the directory that contains the desired parcel. If the directory is correct, but no manifest.json file is present, then you can self-host the parcel(s) for the product and generate your own manifest.json file. See <a href="The parcel repository format">The parcel repository format</a> on the Cloudera GitHub site for the specification of a parcel repository, including for the manifest.json file.

### Seeking Help

Third-party products distributed via parcel for use with Cloudera Manager are supported by Cloudera partners. This support includes providing the necessary information for installing their products using CSDs and parcels, describing required service and role configurations, and general documentation on using the products. Please contact Cloudera partners' support organizations for help with any of these items.

# Creating and Modifying Clusters with the Cloudera Director Web UI

Before initially launching a CDH cluster, you can use the Cloudera Director web UI to add, delete, or modify the default roles and instance groups. You can also add, remove, or repair instances in an existing cluster.

## Configuring Instance Groups During Cluster Creation

An instance group is a collection of roles that are installed together on one or more instances. When Cloudera Director creates a CDH cluster, it includes three default instance groups: masters, workers, and gateway. Each of these instance groups contains roles of the type represented by that instance group, for the CDH services selected for the cluster. For example, if your cluster includes HDFS and YARN, the masters instance group includes the following roles:

- For HDFS NameNode, SecondaryNameNode, Balancer
- For YARN ResourceManager, JobHistory Server

The workers instance group will include the following roles:

- For HDFS DataNode
- For YARN NodeManager

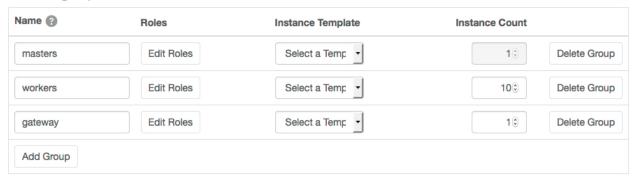

The gateway instance group includes a gateway role for HDFS and another for YARN.

For an introduction to master, worker, and gateway roles, see the Cloudera Manager 5 Overview.

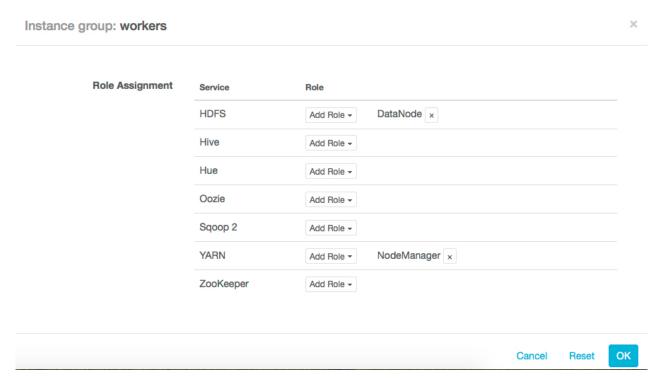

Although the default instance groups are automatically configured with roles of a given type (masters, workers, or gateway), you can add any kind of role to any instance group.

When you create a cluster with Cloudera Director, a default set of instance groups and roles, based on the CDH services you include, is displayed in the Instance Groups section of the Add Cluster page:

### Instance groups

By clicking **Edit Roles**, you can see the roles included in each instance group. These roles will be installed on each instance running that instance group. In this example, by clicking Edit Roles for the workers instance group above, you can see that each of the 10 instances that will be installed for the workers instance group will include two roles, an HDFS DataNode and a YARN NodeManager:

You can modify the default configuration of instance groups during cluster creation by doing the following:

- Change the number of instances for an instance group by clicking the up or down arrows.
- Delete an instance group by clicking Delete Group at the right end of the row for that instance group.
- Add roles to an existing instance group by clicking Edit Roles and then Add Role. Available roles for the services in the cluster are displayed. Click a role to add it to the instance group.
- Add another instance group to the cluster by clicking Add Group, entering a name for the instance group and assigning roles to it, selecting an instance template, and clicking the up or down arrows to choose the number of instances to install.

## Modifying the Number of Instances in an Existing Cluster

Cloudera Director can grow or shrink the size of an existing cluster by adding or removing instances.

### Adding Instances to a Cluster

- 1. Log in to Cloudera Director at http://director-server-hostname: 7189. Cloudera Director opens on the All Environments page, which displays the current environments, deployments, and clusters. Click the cluster you want to modify.
- 2. Click Modify Cluster to the right of the cluster name. The Modify Cluster page displays the gateway, masters, and workers instance groups and any additional instance groups that have been added to the cluster, with the current number of instances in each instance group.
- 3. You can add instances to an existing instance group or create a new instance group and add roles to it.
  - To add instances to an existing instance group, click Edit to the right of the instance group and click the up or down arrows in the Add Instances section to increase the number of workers and gateways to the desired size. Each new instance will contain the same roles as the existing instances of that group.
  - To create a new instance group, click Add Group, enter a name for the instance group, assign roles to it, select an instance template, and click the up or down arrows to choose the desired number of instances of that group to add.

Note: Cloudera recommends rebalancing the cluster through Cloudera Manager if you increase the number of HDFS DataNodes by 30% or more. For more information, see Rebalancing the Cluster After Adding or Removing Instances on page 214.

### Ensure Consistency of Instances before Modify Operations

Operations that modify a cluster, such as grow and clone operations, require all the instances in an instance group to be consistent, that is, to have the same role assignments and configurations in Cloudera Manager, and the same properties, such as instance type and image, in the cloud provider.

With Cloudera Director 2.5 and higher, the cluster refresher will detect changes to the instances in Cloudera Manager and in the cloud provider. If the instances in an instance group are inconsistent, the UI will flag the inconsistent instances and prevent grow operations on the cluster. During this time, clone operations on the cluster will fail. Using Cloudera Manager or your cloud provider's tools, you must change role assignments or configurations, or change properties in the cloud provider, such as instance type or image, to make the instances in your instance groups consistent. Once all the instances in the virtual instance group are consistent, the instance template will be updated, and subsequent grow operations on the group, or clone operations on the cluster, will use the new role assignments and configurations, and the new cloud provider properties.

If you are unable to make the instances consistent, you can use the following workarounds. If you created your cluster from a configuration file, you can edit the configuration file before using it to create a new cluster. And if you created the cluster via the UI, you can use the export functionality to get a configuration file, and edit that configuration file to create a new cluster with consistency of instances within instance groups.

### Removing Instances from a Cluster

- 1. Log in to Cloudera Director at http://director-server-hostname:7189. Cloudera Director opens on the All Environments page, which displays the current environments, deployments, and clusters. Click the cluster you want to modify.
- 2. Click Modify Cluster to the right of the cluster name. The Modify Cluster page displays the gateway, masters, and workers instance groups and any additional instance groups that have been added to the cluster, with the current number of instances in each instance group.
- 3. You can remove an entire instance group, including all of its instances, or remove individual instances from an instance group:
  - To remove an entire instance group, click **Delete Group** at the right end of the row for that instance group.
  - To remove individual instances from an instance group, click Edit near the right end of the row for the instance group. Click the checkbox for each instance you want to remove, and click the **Delete** button. The instances you select display an action status of **To be deleted**.
- 4. Click OK to continue, Reset to unselect the selected instances and make a new selection, or Cancel to stop without making any changes.
- **5.** Click **Continue** to confirm and delete the selected instances.

### Note:

- It is important to maintain the number of HDFS DataNode role instances at or above the HDFS replication factor configured for the cluster. By default, Cloudera recommends a replication factor of three.
- Cloudera Director decommissions instances before removing them from the cluster. When decommissioning an HDFS DataNode, Cloudera Manager moves all the blocks from that instance to other instances so that the replication factor is maintained, and there is no risk of data loss.
- You cannot delete an instance with an HDFS DataNode if the number of DataNodes equals the replication factor (which by default is three) of any file stored in HDFS. For example, if the replication factor of any file is three, and you have three DataNodes, you cannot delete an instance with a DataNode.
- Cloudera recommends rebalancing the cluster through Cloudera Manager if you reduce the number of HDFS DataNodes by 30% or more. For more information, see Rebalancing the Cluster After Adding or Removing Instances on page 214.

### Rebalancing the Cluster After Adding or Removing Instances

After you add or remove instances from a cluster, HDFS data is likely to be distributed unevenly across DataNodes. Cloudera Director does not rebalance HDFS when you add instances or remove them from the cluster. If you need to rebalance the cluster, you must do so manually as described in <u>HDFS Balancers</u> in the Cloudera Manager documentation.

The need for rebalancing depends on the amount of data in HDFS and the number of instances added or removed during the cluster. Rebalancing is required only when there is a large movement of data. Cloudera recommends rebalancing the cluster through Cloudera Manager if you increase or reduce the number of DataNodes by 30% or more.

## Repairing Worker and Gateway Instances in a Cluster

- 1. Log in to Cloudera Director at http://director-server-hostname:7189 Cloudera Director opens on the All Environments page, which displays the current environments, deployments, and clusters. Click the cluster you want to modify.
- 2. Click Modify Cluster to the right of the cluster name. The Modify Cluster page displays the gateway, masters, and workers instance groups and any additional instance groups that have been added to the cluster, with the current number of instances in each instance group.
- 3. Click Edit next to the instance count for workers or gateways to repair, and select the instances to repair.
- 4. Click the Repair button above the list of instances. The instances you selected display an action status of To be repaired.
- 5. Click OK to continue, Reset to unselect the selected instances and make a new selection, or Cancel to stop without making any changes.
- **6.** Click **Continue** to confirm and repair the selected instances.

Note: The above procedure is for worker and gateway roles, not for master roles. Because master roles have state, repairing them requires migrating the roles from one host to another. For information on migrating HDFS master roles, see <u>Using Role Migration to Repair HDFS Master Role Instances</u> on page 170.

# **Post-Creation Scripts**

There are three kinds of post-creation scripts, depending on whether they are for the Cloudera Manager deployment, for a CDH cluster as a whole, or for each instance in a CDH cluster. The scripts can be written in any scripting language that can be interpreted on the system where it runs.

Each type of post-creation script can be specified either by embedding scripts in the configuration file or by including paths to script files on the local filesystem:

- Embedding in the configuration file: For deployment post-creation scripts, include your script in the postCreateScripts section within the cloudera-manager {} configuration block. For cluster post-creation scripts, include your script in the postCreateScripts or instancePostCreateScripts section within the cluster {} configuration block. These blocks can take an array of scripts, similar to the bootstrapScript that can be placed inside the instance {} configuration block.
- Include paths to files on the local filesystem: For deployment post-creation scripts, include the path to a script in the postCreateScriptsPaths section within the cloudera-manager {} configuration block. For cluster post-creation scripts, include your script in the postCreateScripts or instancePostCreateScripts section within the cluster {} configuration block. You can provide an array of paths to arbitrary files on the local filesystem. This is similar to the bootstrapScriptPath directive. Cloudera Director reads the files from the filesystem and uses their contents as post-creation scripts.

Post-creation scripts are available through the configuration file or the Cloudera Director API, but not through the Cloudera Director web UI.

### Deployment Post-creation Scripts

Deployment-level post-creation scripts run as root on the Cloudera Manager instance when Cloudera Manager deployment is completed. They are configured in the cloudera-manager section of the configuration file in the section postCreateScripts.

Deployment-level post-creation scripts can be used to customize the Cloudera Manager instance after a cluster has been created, for example, to add a package or modify a file on the Cloudera Manager instance.

Multiple post-creation scripts can be supplied. They will run in the order they are listed in the configuration file.

The following code block is an excerpt from the reference configuration file on the Cloudera github site:

```
cloudera-manager {
    postCreateScripts: ["""#!/bin/sh
# This is an embedded post-creation script that runs as root and can be used to
# customize the Cloudera Manager instance after the deployment has been created.
# If the exit code is not zero Cloudera Director will fail
# Post-creation scripts also have access to the following environment variables:
     DEPLOYMENT_HOST_PORT
    ENVIRONMENT_NAME
#
#
     DEPLOYMENT_NAME
     CM USERNAME
#
     CM_PASSWORD
echo 'Hello World!'
exit 0
    . . .
    """#!/usr/bin/python
# Additionally, multiple post-creation scripts can be supplied. They will run
# in the order they are listed here. Interpeters other than bash can be used
# as well.
print 'Hello again!'
    """]
    # For more complex scripts, post-creation scripts can be supplied via local
    # filesystem paths. They will run after any scripts supplied in the previous
    # postCreateScripts section.
    # postCreateScriptsPaths: ["/tmp/test-script.sh",
    #
                              "/tmp/test-script.py"]
}
```

### **Cluster Post-creation Scripts**

There are two types of cluster post-creation scripts:

- A cluster-level script is run on a single arbitrary instance in the cluster.
- An *instance-level script* is run on each instance in the cluster.

As with deployment-level scripts, cluster post-creation scripts can be specified either by embedding scripts in the configuration file or by including paths to script files on the local filesystem. For both instance-level and cluster-level scripts (and unlike bootstrapScript and bootstrapScriptPath), both post-creation scripting methods can be used simultaneously. For example, postCreateScripts could be used for setup (package installation, light system configuration), and postCreateScriptsPaths could be used to refer to more complex scripts that may depend on the configuration that was performed in postCreateScripts.

Instance-level and cluster-level scripts run when bootstrapping is complete and the cluster is ready. Instance-level scripts will also be run when you grow a cluster by adding instances, but will not run when instances are migrated manually. For instance-level and cluster-level scripts, where there can be multiple instancePostCreateScripts and postCreateScripts, the scripts run in the following order:

- 1. Everything in the instancePostCreateScripts block is run sequentially.
- 2. Everything in instancePostCreateScriptsPaths is run sequentially.
- **3.** Everything in the postCreateScripts block is run sequentially.
- **4.** Everything in postCreateScriptsPaths is run sequentially.

### Cluster-level Post-creation Scripts

Cluster-level post-creation scripts run as root on a single arbitrary instance in a cluster after the cluster has been created. As with instance-level post-creation scripts, they are configured in the cluster section of the configuration file. They run after any instance post-creation scripts.

The following code block is an excerpt from the reference configuration file on the Cloudera github site:

```
cluster {
    postCreateScripts: ["""#!/bin/sh
# This is an embedded post-creation script that runs as root and can be used to
# customize the cluster after it has been created. This will run only once,
# at a cluster level, on an arbitrary cluster instance.
# If the exit code is not zero Cloudera Director will fail
# Post-creation scripts also have access to the following environment variables:
     DEPLOYMENT_HOST_PORT
     ENVIRONMENT_NAME
#
#
    DEPLOYMENT NAME
#
     CLUSTER NAME
#
     CM_USERNAME
     CM_PASSWORD
echo 'Hello World!'
exit 0
    """#!/usr/bin/python
# Additionally, multiple post-creation scripts can be supplied. They will run
# in the order they are listed here. Interpeters other than bash can be used
# as well.
print 'Hello again!'
    # For more complex scripts, post-creation scripts can be supplied via local
    # filesystem paths. They will run after any scripts supplied in the previous
    # postCreateScripts section.
    # postCreateScriptsPaths: ["/tmp/test-script.sh",
```

```
"/tmp/test-script.py"]
}
```

#### Instance-level Post-creation Scripts

Instance-level post-creation scripts run as root after a cluster has been created. They are configured in the cluster section of the configuration file.

They run before any cluster-level post-creation scripts. Instance-level post-creation scripts can be used, for example, to specify processes that have to be run separately on each instance, such as to add a package to all cluster instances or modify a file on all cluster instances.

The following code block is an excerpt from the <u>reference configuration file</u> on the Cloudera github site:

```
cluster {
    instancePostCreateScripts: ["""#!/bin/sh
# This is an embedded instance post-creation script that runs as root and can be used
# customize each cluster instance after the cluster has been created. This script will
# on every cluster instance. These scripts run before postCreateScripts, which are at
cluster level.
# If the exit code is not zero Cloudera Director will fail
# Instance post-creation scripts also have access to the following environment variables:
     DEPLOYMENT_HOST_PORT
     ENVIRONMENT_NAME
#
     DEPLOYMENT_NAME
#
     CLUSTER_NAME
#
     CM_USERNAME
#
    CM_PASSWORD
echo 'Hello World!'
exit 0
    """#!/usr/bin/python
# Additionally, multiple instance post-creation scripts can be supplied. They will run
# in the order they are listed here. Interpeters other than bash can be used
# as well.
print 'Hello again!'
   # For more complex scripts, instance post-creation scripts can be supplied via local
    # filesystem paths. They will run after any scripts supplied in the previous
    # instancePostCreateScripts section.
    # instancePostCreateScriptsPaths: ["/tmp/test-script.sh",
                              "/tmp/test-script.py"]
}
```

## Predefined Environment Variables

As noted in the code comments above, post-creation scripts have access to several environment variables defined by Cloudera Director. Use these variables in your scripts to communicate with Cloudera Manager and configure it after Cloudera Director has completed its tasks.

Deployment-level post-creation scripts do not use the cluster name variable, since they can include multiple clusters.

Variable Name	Example	Description
DEPLOYMENT_HOST_PORT	192.168.1.100:7180	The host and port used to connect to the Cloudera Manager deployment that this cluster belongs to.
ENVIRONMENT_NAME	director_environment	The name of the environment that this cluster belongs to.
DEPLOYMENT_NAME	director_deployment	The name of the Cloudera Manager deployment that this cluster belongs to.
CLUSTER_NAME	director_cluster	The name of the cluster. The Cloudera Manager API needs this to specify which cluster on a Cloudera Manager server to operate on.  Note: This variable is not available for deployment-level post-creation scripts, since Cloudera Manager deployments are not necessarily associated with a particular cluster.
CM_USERNAME	admin	The username needed to connect to the Cloudera Manager deployment.
CM_PASSWORD	admin	The password needed to connect to the Cloudera Manager deployment.

# Terminating a Cluster

You can terminate a cluster at any time using either the web UI or the CLI.

## Terminating a Cluster with the web UI

To terminate a cluster with the web UI:

- **1.** Log in to Cloudera Director. For example, http://cloudera\_director\_host:7189. Cloudera Director opens with a list of clusters.
- 2. Click the Actions dropdown arrow for the cluster you want to terminate and click **Terminate**.
- **3.** In the confirmation dialog box, click **Terminate** to terminate the cluster.

## Terminating a Cluster with the CLI

For information on terminating a cluster with the CLI, see the section on the terminate-remote command in Commands on page 13.

# Using the Cloudera Director Client

The Cloudera Director client works well for proof-of-concept demonstrations, development work, and infrequent usage. Deployment through the Cloudera Director client involves installing on an instance, editing a configuration file, and running Cloudera Director from the command line. Cloudera Director client installation, configuration, and use are described in the following topics.

# Installing Cloudera Director Client

To install Cloudera Director client in standalone mode, without Cloudera Director server, perform the tasks below. You must be either running as root or using sudo to perform these tasks.

For instructions on installing Cloudera Director client together with Cloudera Director server, see the following:

- For AWS, see Installing Cloudera Director Server and Client on the EC2 Instance on page 52.
- For Google Cloud Platform, see Installing Cloudera Director Server and Client on Google Compute Engine on page 68.

Important: Cloudera Director requires a JDK. For more information, see Supported Software and Distributions on page 43.

 Install a supported version of the Oracle Java Development Kit (JDK) on the Cloudera Director host. Currently, Cloudera Director supports JDK versions 7 and 8.

Note: Spark 2.2 requires JDK 8 and Python 2.7 or higher. For information on using Java 8 with Cloudera Director, see **Deploying a Java 8 Cluster**.

For installation information, see <u>Java SE Downloads</u>.

- 2. Download Cloudera Director by running the correct commands for your distribution.
  - For RHEL 6 and CentOS 6:

cd /etc/yum.repos.d/ sudo wget "https://archive.cloudera.com/director/redhat/6/x86\_64/director/cloudera-director.repo"

For RHEL 7 and CentOS 7:

cd /etc/yum.repos.d/ sudo wget "https://archive.cloudera.com/director/redhat/7/x86\_64/director/cloudera-director.repo"

For Ubuntu 14.04 (Trusty Tahr):

cd /etc/apt/sources.list.d sudo wget "https://archive.cloudera.com/director/ubuntu/trusty/amd64/director/cloudera-director.list"

- **3.** Add the signing key.
  - For RHEL 6, CentOS 6 this step is not required. Continue to the next step.
  - For RHEL 7, CentOS 7 this step is not required. Continue to the next step.
  - For Ubuntu 14.04 (Trusty Tahr), run the following command:

curl -s "https://archive.cloudera.com/director/ubuntu/trusty/amd64/director/archive.key" sudo apt-key add -

**4.** Install Cloudera Director client by running the correct command for your distribution.

For RHEL 6 and CentOS 6:

yum install cloudera-director-client

For RHEL 7 and CentOS 7:

yum install cloudera-director-client

For Ubuntu 14.04 (Trusty Tahr):

apt-get install cloudera-director-client

## Provisioning a Cluster on AWS

The configuration file contains information Cloudera Director needs to operate and settings that define your cluster. The Cloudera Director configuration file is in HOCON format. For information on HOCON, see the documentation at https://github.com/typesafehub/config/blob/master/HOCON.md.

Sample configuration files are found either in /usr/lib64/cloudera-director/client or /usr/lib/cloudera-director/client, depending on the operating system you are using. Copy the sample files to your home directory before editing them.

To modify the configuration file:

1. Rename the aws.simple.conf file to cluster.conf. For advanced cluster configuration, use aws.reference.conf.

**Note:** The configuration file must use the .conf file extension.

- 2. Open cluster.conf with a text editor.
- **3.** Configure the basic settings:
  - name change to something that makes the cluster easy to identify.
  - id leave this set to aws.
  - accessKeyId AWS access key ID. Make sure the value is enclosed in double quotes.
  - secretAccessKey AWS secret access key. Make sure the value is enclosed in double quotes.
  - **region** specify the region (for example, us-west-2).
  - keyName specify the name of the key pair used to start the cluster launcher. Key pairs are region-specific. For example, if you create a key pair (or import one you have created) in US-West-2, it will not be available in US-West-1. For information on creating key pairs in Amazon EC2 or importing existing key pairs, see Amazon EC2 Key Pairs.
  - **subnetId** ID of the subnet that you noted earlier.
  - · securityGroupsIds ID of the security group that you noted earlier. Use the ID of the group, not the name (for example, sg-b139d3d3, not default).
  - instanceNamePrefix enter the prefix to prepend to each instance's name.
  - image specifies the AMI to use. Cloudera recommends Red Hat Enterprise Linux 6.4 (64bit). To find the correct AMI for the selected region, visit the Red Hat AWS Partner page.

Note: If you use your own AMI, make sure to disable any software that prevents the instance from rebooting during the deployment of the cluster.

**4.** Configure the following cluster settings:

- a. You can only use Cloudera Manager 5. No changes are needed for repository and repository key URLs and you must set the parcel repositories to match the CDH and Impala versions you plan to install.
- b. Specify services to start on the cluster. For a complete list of allowed values, see the Cloudera Manager API Service Types.

Note: Include Flume in the list of services only when customizing role assignments. See the configuration file (aws.reference.conf) included in the Cloudera Director download for examples on how to configure customized role assignments. If Flume is required, it should be excluded from the list of services in the configuration file and added as a service using Cloudera Manager web UI or API after the cluster is deployed. When adding Flume as a service, you must assign Flume agents (which Cloudera Manager does not do automatically).

- c. Specify the number of instances in the cluster.
- 5. Save the file and exit.

With Cloudera Director 2.2 and later, you can use the validate CLI command to check your configuration file's settings for environments, deployments, and clusters. For more information, see the entry for validate on the page Cloudera Director Interfaces.

Note: If your root disk drive is larger than all the other drives on the machine, Cloudera Manager automatically installs HDFS on the root drive. You can change this behavior with an explicit override in the configs {} block within the cluster {} section of the configuration file.

# Running Cloudera Director Client

After you modify the configuration file, you can run Cloudera Director client. There are two ways of running the Cloudera Director client:

- In standalone mode, using the bootstrap command. Clusters created using the bootstrap command cannot be managed using the Cloudera Director web UI. The information below on this page concerns running the client in standalone mode.
- If you already have a server, you can run the client against the server using the commands bootstrap-remote and terminate-remote. Only clusters created with the bootstrap-remote command can be managed using the Cloudera Director web UI. For more information on using the client to deploy clusters on the server, see Submitting a Cluster Configuration File.

**Note:** If you are restarting Cloudera Director client, you are prompted to resume from where the client stopped or start over. If you made changes to the configuration file between deployments, or if you need to start the run from scratch, you should start over.

**1.** From the cluster launcher, enter the following:

```
[ec2-user@ip-10-1-1-18]$ cloudera-director bootstrap cluster.conf
```

Cloudera Director displays output similar to the following:

```
Installing Cloudera Manager ...
* Starting ... done
* Requesting an instance for Cloudera Manager ...... done
* Inspecting capabilities of 10.1.1.194 ...... done
* Normalizing 10.1.1.194 ..... done * Installing python (1/4) .... done
* Installing ntp (2/4) .... done
* Installing curl (3/4) .... done
```

```
* Installing wget (4/4) ..... done
* Installing repositories for Cloudera Manager ...... done
* Installing jdk (1/5) ..... done
 Installing cloudera-manager-daemons (2/5) ..... done
* Installing cloudera-manager-server (3/5) ..... done
* Installing cloudera-manager-server-db-2 (4/5) ..... done
 Installing cloudera-manager-agent (5/5) .... done
* Starting embedded PostgreSQL database ..... done
* Starting Cloudera Manager server ..... done
 Waiting for Cloudera Manager server to start \dots done
 Configuring Cloudera Manager ..... done
* Starting Cloudera Management Services ..... done
* Inspecting capabilities of 10.1.1.194 ...... done
* Done ...
Cloudera Manager ready.
Creating cluster C5-Sandbox-AWS ...
 Starting ... done
* Requesting 3 instance(s) ..... done
* Inspecting capabilities of new instance(s) ..... done
 Running basic normalization scripts ..... done
* Registering instance(s) with Cloudera Manager \dots done
* Waiting for Cloudera Manager to deploy agents on instances ... done
* Creating CDH5 cluster using the new nodes \ldots\ldots done
* Downloading CDH-5.4.0-1.cdh5.4.0.p0.26 parcel ..... done
* Distributing CDH-5.4.0-1.cdh5.4.0.p0.26 parcel ... done
* Activating CDH-5.4.0-1.cdh5.4.0.p0.26 parcel ..... done
* Done ...
Cluster ready.
```

Note: If you have a large root disk partition or if you are using a hardware virtual machine (HVM) AMI, the instances can take a long time to reboot. Cloudera Manager can take 20-25 minutes to become available.

2. To monitor Cloudera Director, log in to the cluster launcher and view the application log:

```
$ ssh ec2-user@54.186.148.151
Last login: Tue Mar 18 20:33:38 2014 from 65.50.196.130
[ec2-user@ip-10-1-1-18]$ tail -f ~/.cloudera-director/logs/application.log
[...]
```

**Note:** If you have deployment issues and need help troubleshooting, be careful when distributing the state.h2.db or application.log files. They contain sensitive information, such as your AWS keys and SSH keys.

# Connecting to Cloudera Manager with Cloudera Director Client

After the cluster is ready, log in to Cloudera Manager and access the cluster.

To access Cloudera Manager:

1. Use the status command to get the host IP address of Cloudera Manager:

```
$ cloudera-director status cluster.conf
```

Cloudera Director displays output similar to the following:

```
Cloudera Director 2.0.0 initializing ...
Cloudera Manager:
```

```
* Instance: 10.0.0.110 Owner=wintermute, Group=manager
* Shell: ssh -i /root/.ssh/launchpad root@10.0.0.110
Cluster Instances:
* Instance 1: 10.0.0.39 Owner=wintermute, Group=master
* Shell 1: ssh -i /root/.ssh/launchpad root@10.0.0.39
* Instance 2: 10.0.0.148 Owner=wintermute, Group=slave
* Shell 2: ssh -i /root/.ssh/launchpad root@10.0.0.148
* Instance 3: 10.0.0.150 Owner=wintermute, Group=slave
* Shell 3: ssh -i /root/.ssh/launchpad root@10.0.0.150
* Instance 4: 10.0.0.147 Owner=wintermute, Group=slave
* Shell 4: ssh -i /root/.ssh/launchpad root@10.0.0.147
 Instance 5: 10.0.0.149 Owner=wintermute,Group=slave
 Shell 5: ssh -i /root/.ssh/launchpad root@10.0.0.149
* Instance 6: 10.0.0.151 Owner=wintermute, Group=slave
 Shell 6: ssh -i /root/.ssh/launchpad root@10.0.0.151
* Instance 7: 10.0.0.254 Owner=wintermute, Group=gateway
 Shell 7: ssh -i /root/.ssh/launchpad root@10.0.0.254
* Instance 8: 10.0.0.32 Owner=wintermute, Group=master
 Shell 8: ssh -i /root/.ssh/launchpad root@10.0.0.32
* Instance 9: 10.0.0.22 Owner=wintermute, Group=master
* Shell 9: ssh -i /root/.ssh/launchpad root@10.0.0.22
Launchpad Gateway:
* Gateway Shell: ssh -i /path/to/launchpad/host/keyName.pem -L 7180:10.0.0.110:7180 -L
7187:10.0.0.110:7187 root@ec2-54-77-57-3.eu-west-1.compute.amazonaws.com
Cluster Consoles:
 Cloudera Manager: http://localhost:7180
* Cloudera Navigator: http://localhost:7187
```

In this example, the host IP address is 10.0.0.110.

**2.** Change to the directory where your *keyfile*. pem file is located. Then, route the connection over SSH:

```
$ ssh -L 7180:cm-host-private-ip:7180 ec2-user@director-client-public-ip
# go to http://localhost:7180 in your browser and login with admin/admin
```

**Note:** If you get a permission error, add the .pem file from the command line:

```
$ ssh -i <keyfile.pem> -L 7180:cm-host-private-ip:7180
ec2-user@cm-host-public-ip
```

- 3. Open a web browser and enter http://localhost:7180 to connect to Cloudera Manager. Use admin as both the username and password.
- 4. Add any additional services to the cluster. The CDH 5 parcel was already distributed by Cloudera Director.

# Modifying a Cluster with the Configuration File

This section describes how to make changes to the cluster through Cloudera Director, using the client and the configuration file.

## Growing or Shrinking a Cluster with the Configuration File

After launching a cluster with the bootstrap command (using the stand-alone Cloudera Director client), you can add or remove instances with the update command:

## Using the Cloudera Director Client

- 1. Open the cluster.conf file that you used to launch the cluster.
- 2. Change the value for the type of instance you want to change. For example, the following increases the number of workers to 15:

```
workers {
      count: 15
      minCount: 5
      instance: ${instances.hs18} {
        tags {
          group: worker
      }
```

**3.** Enter the following command:

```
cloudera-director update cluster.conf
```

Cloudera Director increases the number of worker instances.

4. Assign roles to the new master instances through Cloudera Manager. Cloudera Director does not automatically assign roles.

Note: If you create a cluster with Cloudera Director server using the bootstrap remote command, you cannot modify the cluster with the CLI, but only with the Cloudera Director web UI.

#### Rebalancing the Cluster After Adding or Removing Hosts

After hosts have been added to or removed from a cluster, HDFS data is likely to be distributed unevenly across DataNodes. Cloudera Director does not rebalance HDFS when you add hosts or remove them from the cluster, so after growing or shrinking the cluster, you must perform manual rebalances in Cloudera Manager, as described in the Cloudera Manager documentation, HDFS Balancers.

The need for rebalancing depends on the amount of data in HDFS and the number of hosts added or removed during the cluster. Cloudera Director decommissions hosts before removing them from the cluster during a shrink operation. As part of decommissioning a DataNode, Cloudera Manager will move all the blocks from that host to other hosts so that the replication factor will be maintained even after the hosts are decommissioned. So there is no risk of data loss if the cluster is shrunk by more than two instances at a time. Rebalancing is necessary so that the blocks are placed in an optimal manner and is not required when a small number of hosts have been removed from a cluster, but only when there has been a large movement of data.

# **Upgrading Cloudera Director**

This section contains notes and procedures for upgrading Cloudera Director.

## Before Upgrading Cloudera Director

Follow these steps before upgrading Cloudera Director.

1. Let running operations finish.

For example, if Cloudera Director is setting up a Cloudera Manager or CDH cluster (indicated by a progress bar in the web UI), an upgrade will not complete successfully. An error in the log file instructs you to use the old version of Cloudera Director until all running operations are completed, and then perform the upgrade.

**2.** Back up the Cloudera Director database that stores state information.

By default, this is the embedded H2 database at /var/lib/cloudera-director-server/state.h2.db.

If you are using a MySQL database to store the Cloudera Director state, use MySQL backup procedures to back up the Cloudera Director database. The following example shows how to do this using the mysqldump utility:

```
mysqldump --all-databases --single-transaction --user=root --password > backup.sql
```

For more information on using mysqldump, see the MySQL documentation.

**3.** If upgrading from Cloudera Director 1.1, change your default encryption key.

After an upgrade from Cloudera Director 1.1 to a higher version, any new data that Cloudera Director persists in its database is encrypted with a default encryption key. For increased security, Cloudera recommends that you change your encryption key in the application.properties file after performing an upgrade from 1.1 to a higher version. The file is located at /etc/cloudera-director-server/application.properties.

For more information about encryption and Cloudera Director data, see Cloudera Director Database Encryption on page 132.

## Changes to the application.properties File

If you modified your existing application. properties file, the result of upgrading depends on which version of Linux you are using:

- RHEL and CentOS When new properties are introduced in Cloudera Director, they are added to application.properties.rpmnew. The original application.properties file functions as before and is not overwritten with the new Cloudera Director version properties. You do not need to copy the new properties from application.properties.rpmnew to the old application.properties file.
- Ubuntu The modified Cloudera Director application.properties file is backed up to a file named application.properties.dpkg-old. The original application.properties file is then overwritten by the new application.properties file containing new Cloudera Director properties. After upgrading, copy your changes from application.properties.dpkg-old to the new application.properties file.

## Requirements for Cloudera Director 2.0 and Higher

The following are requirements for running Cloudera Director 2.0 and higher:

- Cloudera Director 2.0 and higher support the following Linux operating systems:
  - RHEL and CentOS 6.5, 6.7, and 7.1
  - Ubuntu 14.04

Note: See Requirements and Supported Versions for the latest information about operating system versions supported by versions of Cloudera Director.

- Cloudera Director now requires Oracle JDK (Oracle Java SE Development Kit) version 7 or 8. Java 6 is not supported.
- Cloudera Director 2.0 and higher can install any version of Cloudera Manager 5 with any CDH 5 parcels. Note that the Cloudera Manager minor version must the same as or higher than the CDH minor version. For instance, Cloudera Manager 5.7 can be used to launch and manage a CDH 5.5 cluster but not with a CDH 5.10. Cloudera Manager 4 and CDH 4 are not supported. Use of CDH packages is not supported.

If you are running a lower version of Cloudera Director on an operating system that is not supported for Cloudera Director 2.0, you cannot upgrade to Cloudera Director 2.0 or higher.

For complete requirements for Cloudera Director, see Requirements and Supported Versions.

## Changes in Cloudera Director 2.0 and Higher

- Cloudera Director 2.0 and higher requires Oracle JDK (Oracle Java SE Development Kit) version 7 or 8. Java 6 is not supported.
- Cloudera Director 2.0 and higher can install any version of Cloudera Manager 5 with any CDH 5 parcels. Cloudera Manager 4 and CDH 4 are not supported. Use of CDH packages is not supported.

## Handling Modified Plug-in Configuration Files

Cloudera Director includes plug-in configuration files that enable you to configure how the plug-ins work. The following plug-in files are located in directories in /var/lib/cloudera-director-plugins/:

- aws-provider-version
- azure-provider-version
- byon-provider-example-version
- google-provider-version
- sandbox-provider-version

The location for plug-in configuration files has changed starting with Cloudera Director 2.0. In Cloudera Director 1.5.x and lower, they are located at /var/lib/cloudera-director-server/plugins. In Cloudera Director 2.0 and higher, they are located at /var/lib/cloudera-director-plugins/.

You do not normally need to modify the plug-in configuration files, but if you have modified any of them, your modifications will be overwritten during an upgrade. Before running the upgrade command, back up the modified files to another location. Then, after upgrading, redo your modifications in the new version of the file. These steps are included in the upgrade procedures below.

# **Upgrading Cloudera Director**

The following sections describe steps for upgrading Cloudera Director on supported Linux operating systems.

Note: Cloudera Director 2.5 will fail to start after upgrading from 2.4 if a cluster contains a heterogeneous instance group. To resolve this problem, find heterogeneous instance groups displayed in the Cloudera Director UI. Resolve any inconsistencies within each instance group to restore homogeneity before upgrading Cloudera Director from 2.4 to 2.5. For more information about how to resolve heterogeneous instance groups, see Ensuring Consistency of Virtual Instance Groups.

### **RHEL and CentOS**

1. Stop the Cloudera Director server service by issuing the following command:

sudo service cloudera-director-server stop

- 2. Cloudera Director 2.1.x and higher require Java 7 or 8. If you must upgrade your version of the Java SDK to meet this requirement, do so now.
- 3. Update your Cloudera Director . repo file (the yum repository configuration file) to point to the version of Cloudera Director you are upgrading to by doing one of the following:
  - Open /etc/yum.repos.d/cloudera-director.repo. The baseurl value in this file now points to your current version of Cloudera Director, such as /1 or /2 (and may include a specific minor or maintenance release version, such as /1.1, /1.1.3, /2.2.0, or /2.2. Update the baseurl value to point to the new version, /2.

**Note:** Cloudera software version numbers take the form major\_release.minor\_release.maintenance\_release. If there is no major or minor release number, as in /2, the latest version of 2.x is used.

In the absence of a minor version

 Instead of editing your existing .repo file, you can download a new Cloudera Director .repo file, which will point to the latest version of Cloudera Director:

```
cd /etc/yum.repos.d/
sudo wget "https://archive.cloudera.com/director/redhat/7/x86_64/director/cloudera-director.repo"
```

To upgrade to a version of Cloudera Director other than the latest version, you can edit the newly downloaded .repo file as described in the previous bullet point.

- 4. If you have not modified the plug-in configuration files, skip to the next step. If you modified any configuration files in /var/lib/cloudera-director-plugins/plug-in\_name-version (or, for Cloudera Director 1.5 or lower, in /var/lib/cloudera-director-server/plugins/plug-in\_name-version), back them up to another location and remove them from this location before running the upgrade command.
- **5.** Issue the following commands:

```
sudo yum clean all
sudo yum update cloudera-director-server cloudera-director-client
```

- 6. If you have not modified any configuration files, skip to the next step. If you modified any configuration files, restore your backed up files now to /var/lib/cloudera-director-plugins/plug-in\_name-new\_version, before restarting the Cloudera Director server.
- 7. Restart the Cloudera Director server:

sudo service cloudera-director-server start

**Note:** Installing the Cloudera Director server and client packages will automatically install the required plug-in package.

### Ubuntu

1. Stop the Cloudera Director server service by issuing the following command:

sudo service cloudera-director-server stop

## Upgrading Cloudera Director

- 2. Cloudera Director 2.1.x and higher require Java 7 or 8. If you must upgrade your version of the Java SDK to meet this requirement, do so now.
- 3. Update your Cloudera Director cloudera-director.list file (the repository configuration file) to point to the version of Cloudera Director you are upgrading to by doing one of the following:
  - Open /etc/apt/sources.list.d/cloudera-director.list.The baseurl value in this file now points to your current version of Cloudera Director, such as trusty-director1 or trusty-director2 (and may include a specific minor or maintenance release version, such as trusty-director1.1, trusty-director1.1.3, trusty-director2.2, or trusty-director2.2.0). Update the baseurl value to point to the newest version, trusty-director2, if this is not already the current value.

**Note:** Cloudera software version numbers take the form major release.minor release.maintenance release. If there is no major or minor release number, as in trusty-director2, the latest version of 2.x is used.

 Instead of editing your existing cloudera-director.list file, you can download a new Cloudera Director cloudera-director.list file, which will point to the latest version of Cloudera Director:

```
cd /etc/apt/sources.list.d/
```

To upgrade to a version of Cloudera Director other than the latest version, you can edit the newly downloaded cloudera-director.list file as described in the previous bullet point.

- 4. If you have not modified the plug-in configuration files, skip to the next step. If you modified any configuration files in /var/lib/cloudera-director-plugins/plug-in\_name-version (or, for Cloudera Director 1.5 or lower, in /var/lib/cloudera-director-server/plugins/plug-in\_name-version), back them up to another location and remove them from this location before running the upgrade command.
- **5.** Issue the following commands:

```
sudo apt-get clean
sudo apt-get update
sudo apt-get dist-upgrade
sudo apt-get install cloudera-director-server cloudera-director-client
```

- 6. If your original Cloudera Director application. properties file has not been modified, proceed to the next step. If your application.properties file was modified, the original properties file will be overwritten by the new properties file containing new Cloudera Director properties, as described above in Changes to the application.properties File on page 225. Copy your changes from application.properties.dpkg-old to the new application.properties file before restarting the server.
- 7. If you have not modified any configuration files, skip to the next step. If you modified any configuration files, restore your backed up files now to /var/lib/cloudera-director-plugins/plug-in\_name-new\_version, before restarting the Cloudera Director server.
- 8. Restart the Cloudera Director server:

sudo service cloudera-director-server start

Note: Installing the Cloudera Director server and client packages will automatically install the required plug-in package.

## Using IAM Policies with Cloudera Director 1.5 and Higher

In AWS, if you are using an IAM policy to control access to resources in the VPC, Cloudera Director 1.5 and higher requires permission for the method DescribeDBSecurityGroups. To give Cloudera Director permission for this method, add these values to your policy:

```
"Action": [ "rds:DescribeDBSecurityGroups" ],
"Effect": "Allow",
"Resource": ["*"]
```

This permission is required because Cloudera Director 1.5 and higher includes early validation of RDS credentials when creating or updating an environment, whether or not RDS database servers are used.

For a sample IAM policy that includes this permission, see Example IAM Policy on page 193. For more information on AWS IAM, see the <u>IAM User Guide</u> in the AWS documentation.

# **Troubleshooting Cloudera Director**

This topic contains information on problems that can occur when you set up, configure, or use Cloudera Director, their causes, and their solutions.

## Viewing Cloudera Director Logs

To help you troubleshoot problems, you can view the Cloudera Director logs. Log files are in the following locations:

- · Cloudera Director client
  - One shared log file per user account:

\$HOME/.cloudera-director/logs/application.log

- Cloudera Director server
  - One file for all clusters:

/var/log/cloudera-director-server/application.log

Cloudera Director normally logs only error, warning, and informational messages. To configure it to log debug level messages, edit the file logback.xml, which can be found at the following locations:

- Cloudera Director client: /etc/cloudera-director-client/logback.xml
- Cloudera Director server: /etc/cloudera-director-server/logback.xml

The XML file configures the logback logging library. To turn on all debug logging for Cloudera Director and its libraries, change the "root" element as follows:

```
<root level="DEBUG">
```

Enabling debug logging significantly increases the size of the logs, and may include more information than needed for troubleshooting. Once you discover specific loggers that carry information you care most about, you can narrow the scope of debug logging to those only. For example, if after turning on all debug logging you find that the messages emitted from Cloudera Director itself are most important, then you can set the root level back to INFO and then add a new logger element like this example, along with the other similar elements.

```
<logger name="com.cloudera.launchpad" level="DEBUG"/>
```

The logback.xml file can be reconfigured in many other ways to adjust how logging is performed. See Logback configuration in the Logback project documentation to learn more. Note that major changes to log format and contents will hamper the effectiveness of Cloudera support, if you should need to forward logs to them as part of troubleshooting.

### Backing Up the H2 Embedded Database

By default, Cloudera Director uses an H2 embedded database to store environment and cluster data. The H2 embedded database file is located at:

```
/var/lib/cloudera-director-server/state.h2.db
```

Back up the state.h2.db file to avoid losing environment and cluster data. To ensure that your backup copy can be restored, use the H2 backup tools instead of simply copying the file. For more information, see the H2 Tutorial.

### Manual Modifications to the Cloudera Director Database

Manual modifications to the Cloudera Director database are not supported. Modifications made outside of Cloudera Director control can lead to permanent data loss and unrecoverable errors in Cloudera Director.

## Slow or Failed OS Updates in Some AWS Regions

## Symptom

In AWS, Cloudera Director triggers operating system updates and performs software downloads on instances it allocates in your chosen region. Depending on the local network configuration, these updates and downloads may go slowly or

#### Solutions

Consider trying one or more of the following steps:

- Disable instance normalization. This causes Cloudera Director to not perform usual automated, general work on new instances. You should replace that work with your own, either by building a custom AMI with the work already accomplished, or by using a bootstrap script. Normalization can be disabled using a configuration file; contact Cloudera support for guidance on what else you need to do.
- · Create a preloaded AMI. Cloudera Director can avoid downloading Cloudera Manager and CDH software if it is already present in expected locations on instances. This also speeds up deployment and cluster bootstrap processes, even when download speeds from Cloudera repositories are reasonable. See the documentation for more information.
- Mirror Cloudera repositories. Instead of preloading an AMI with Cloudera software, you can host them at local mirrors, and point Cloudera Director to them as alternative download locations. As with preloaded AMIs, taking this step can speed up bootstrap processes, and make your architecture less vulnerable to network problems. See the documentation for more information.

# Cloudera Director Bootstrap Fails with Error Message

### Symptom

Cloudera Director fails to bootstrap with the error message, "DNS is not configured correctly on at least one instance."

Cloudera Director fails to bootstrap the cluster and the Cloudera Agent log (cloudera-scm-agent.log) will show an entry similar to the following:

### Cause

Needs to be diagnosed.

## Solution

Verify that DNS is configured properly. Check the server logs, which may contain additional warning messages and information about why DNS detection failed. For example, this error can appear when an invalid ssh user has been set.

# Cloudera Manager API Call Fails

### Symptom

A Cloudera Manager API call fails in Cloudera Director.

## Troubleshooting Cloudera Director

### Cause

Needs to be diagnosed. (See Solution immediately below.)

#### Solution

Enable API debugging in Cloudera Manager by going to Settings on the Administration tab in Cloudera Manager and clicking the checkbox Enable Debugging of API. Then look at the Cloudera Manager server logs to get more information on why the API call failed.

Note: You can also enable Cloudera Manager API debugging in the configuration file when launching a cluster by setting enable\_api\_debug: true in the Cloudera Manager configs section. The sample configuration file aws.reference.conf has this set by default.

# Cloudera Director Cannot Manage a Cluster That Was Kerberized Through Cloudera Manager

### **Symptom**

Cloudera Director cannot manage a cluster after Cloudera Manager is used to enable Kerberos on the cluster.

#### Cause

Once a cluster is deployed through Cloudera Director, some changes to the cluster that are made using Cloudera Manager cause Cloudera Director to be out of sync and unable to manage the cluster. See Cloudera Director and Cloudera Manager Usage on page 181.

### Solution

Deploy a new kerberized cluster, use distop to transfer data from the old cluster to the new one, and then destroy the old cluster.

## **RDS Name Conflicts**

## Symptom

RDS name conflicts occur when creating multiple clusters with the same configuration file.

## Cause

Most often, deletion of an older RDS instance has not completed when you try to launch a new cluster using the same configuration file, and therefore the same RDS name.

## Solution

Allow more time for an RDS instance to be completely removed before creating a new cluster with the same configuration file, or change the name of the RDS instance in the configuration files for new clusters.

# New Cluster Fails to Start Because of Missing Roles

#### **Symptom**

A new cluster will not start because roles are missing.

#### Cause

Cloudera Director does not validate that all required roles are assigned when provisioning a cluster. This can lead to failures during the intial run of a new cluster. For example, if the gateway instance group was removed, but the Flume Agent and Kafka Broker were assigned to roles in that group, the cluster fails to start.

#### Solution

Ensure that all required role types for the CDH services included in the cluster are assigned to instances before starting the cluster.

# Cloudera Director Server Will Not Start with Unsupported Java Version

### Symptom

Cloudera Director server will not start, and

/var/log/cloudera-director-server/cloudera-director-server.out has the following error:

```
Exception in thread "main" java.lang.UnsupportedClassVersionError:
com/cloudera/launchpad/Server : Unsupported major.minor version 51.0
```

#### Cause

You are running Cloudera Director server against an older, unsupported version of the Oracle Java SE Development Kit (JDK).

### Solution

Update to Oracle JDK version 7 or 8.

# Error Occurs if Tags Contain Unquoted Special Characters

## Symptom

When using the configuration file with the bootstrap command to start Cloudera Director client, or using the bootstrap-remote command to set up a cluster with Cloudera Director server, an error message is displayed. This applies to HOCON characters, and includes periods. If the added configuration is in the form x.y, for example, the following error message may be displayed: "com.typesafe.config.ConfigException\$WrongType: ... <x> has type OBJECT rather than STRING". This means that x.y must be in quotes, as in "x.y".

```
com.typesafe.config.ConfigException$WrongType: ... <x> has type OBJECT rather than STRING
```

### Cause

Cloudera Director validation checks to ensure that special characters in configurations are enclosed in double quotes.

### Solution

Use double quotes for special characters in configurations. An example of a configuration that would require double quotes is "log.dirs" in Kafka.

## **DNS** Issues

### Symptom

Cloudera Director fails to bootstrap a cluster with a DNS error. The Cloudera Agent log (cloudera-scm-agent.log) will show an entry similar to the following:

```
[27/Mar/2017 20:26:16 +0000] 12596 Thread-13 https ERROR Failed to retrieve/store URL:
http://ip-10-202-202-109.ec2.internal:7180/cmf/parcel/download/CDH-5.10.0-1.cdh5.10.0.p0.41-el7.parcel.torrent
/opt/cloudera/parcel-cache/CDH-5.10.0-1.cdh5.10.0.p0.41-el7.parcel.torrent
<urlopen error [Errno -2] Name or service not known>
```

#### Cause

This can be caused by one the following:

- DNS Hostnames is not set to Yes in the Edit DNS Hostnames VPC configuration setting.
- The Amazon Virtual Private Cloud (VPC) is not set up for forward and reverse hostname resolution. Forward and reverse DNS resolution is a requirement for many components of the Cloudera EDH platform, including Cloudera Director.

#### Solutions

In the AWS Management Console, go to Services > Networking and click VPC. In the VPC Dashboard, select your VPC and click Action. In the shortcut menu, click Edit DNS Hostnames and click Yes. If this does not fix the issue, continue with the instructions that follow to configure forward and reverse hostname resolution.

Configure the VPC for forward and reverse hostname resolution. You can verify if DNS is working as expected on a host by issuing the following one-line Python command:

```
python -c "import socket; print socket.getfqdn(); print
socket.gethostbyname(socket.getfqdn())
```

For more information on DNS and Amazon VPCs, see DHCP Options Sets in the Amazon VPC documentation.

If you are using Amazon-provided DNS, perform these steps to configure DHCP options:

- 1. Log in to the AWS Management Console.
- 2. Select VPC from the Services navigation list box.
- **3.** In the left pane, click **Your VPCs**. A list of currently configured **VPCs** is displayed.
- **4.** Select the **VPC** you are using and note the **DHCP options set ID**.
- 5. In the left pane, click **DHCP Option Sets**. A list of currently configured DHCP Option Sets is displayed.
- **6.** Select the option set used by the VPC.
- 7. Check for an entry similar to the following and make sure the domain-name is specified. For example:

```
domain-name = ec2.internal
domain-name-servers = AmazonProvidedDNS
```

Note: If you are using AmazonProvidedDNS in us-east-1, specify ec2.internal. If you are using AmazonProvidedDNS in another region, specify region.compute.internal (for example, ap-northeast-1.compute.internal).

8. If it is not configured correctly, create a new DHCP option set for the specified region and assign it to the VPC. For information on how to specify the correct domain name, see the AWS Documentation.

## Server Does Not Start

## **Symptom**

The Cloudera Director server does not start or quickly exits with an Out of Memory exception.

#### Cause

The Cloudera Director server is running on a machine with insufficient memory.

### Solution

Run Cloudera Director on an instance that has at least 1 GB of free memory. See Resource Requirements on page 44 for more details on Cloudera Director hardware requirements.

## Problem When Removing Hosts from a Cluster

### **Symptom**

A **Modify Cluster** operation fails to complete.

#### Cause

You are trying to shrink the cluster below the HDFS replication factor. See Removing Instances from a Cluster on page 213 (Note) for more information about replication factors.

### Solution

Do not attempt to shrink a cluster below the HDFS replication factor. Doing so can result in a loss of data.

# Problems Connecting to Cloudera Director Server

## **Symptom**

You are unable to connect to the Cloudera Director server.

### Cause

Configuration of security group and iptables settings. For more information about configuring security groups, see Setting up the AWS Environment on page 47. For commands to turn off iptables, see either Installing Cloudera Director Server and Client on the EC2 Instance on page 52 or Installing Cloudera Director Server and Client on Google Compute Engine on page 68. Some operating systems have IP tables turned on by default, and they must be turned off.

## Solution

Check security group and iptables settings and reconfigure if necessary.

# Frequently Asked Questions

This page answers frequently asked questions about Cloudera Director.

## **General Questions**

### Can I move Cloudera Director to a different instance?

In some circumstances, you may want to move Cloudera Director from the instance where it is installed to a different instance. This can be done much as it would be with any other application. One straightforward procedure is to snapshot or image the current instance and deploy a new instance from it.

Cloudera recommends that you take a backup of the database before the migration to be safe. If you are using the H2 embedded database (which is not recommended for production deployments), it resides on the file system, so a snapshot or image will include it. If you are using MySQL to host the Cloudera Director database, then the database resides elsewhere on a database server. Backing up the Cloudera Director database in either case is an extra precaution, but isn't strictly necessary in order to move Cloudera Director over to the new instance.

Note: If you are using MySQL for the Cloudera Director database and the new Cloudera Director instance is in a new subnet, the security rules need to allow instances in the new subnet to reach the MySQL server, whether in a provider database service or elsewhere.

### Can master or worker roles be run on instances where Cloudera Manager is running?

No, CDH cluster entities cannot be run on the same instance as Cloudera Manager.

## How can I reduce the time required for cluster deployment?

You can reduce cluster deployment time by using an Amazon Machine Image (AMI). For information on creating an AMI, see Using Custom Repositories with Cloudera Manager and CDH on page 194.

## How can I make Cloudera Director highly available?

Cloudera Director can set up highly available clusters in a Cloudera Manager deployment, but does not support a high availability setup for itself. You can make Cloudera Director more robust by configuring it to use a backed-up, robust MySQL database server (one that is hosted, for example, on AWS RDS ) for its database instead of Cloudera Director's default H2 database. Then, if the Director instance goes down, another instance can be spun up that references the same database. In this case, Cloudera Director has the ability to resume interrupted work.

For information on setting up highly available clusters in a Cloudera Manager deployment using Cloudera Director, see <u>Creating Highly Available Clusters With Cloudera Director</u> on page 168.

## How do I create instances in multiple availability zones in AWS EC2?

This is AWS-specific. Each subnet exists in only one availability zone, so if you want multiple availability zones for your instances, you need to create multiple instance groups, with each one having a template that points to a different subnet.

#### How can I find a list of available AMIs?

Perform the following steps to generate a list of RHEL 64-bit images:

1. Install the AWS CLI.

\$ sudo pip install awscli

## 2. Configure the AWS CLI.

```
$ aws configure
```

Follow the prompts. Choose any output format. The following example command defines table as the format.

## **3.** Run the following query:

```
aws ec2 describe-images \
  --output table \
--query 'Images[*].[VirtualizationType,Name,ImageId]' \
  --owners 309956199498 \
  --filters \
    Name=root-device-type, Values=ebs \
    Name=image-type, Values=machine \
    Name=is-public,Values=true \
    Name=hypervisor, Values=xen \
    Name=architecture, Values=x86_64
```

AWS returns a table of available images in the region you configured.

# Cloudera Director Glossary

## availability zone

A distinct location in the region that is insulated from failures in other availability zones. For a list of regions and availability zones, see Regions and Availability Zones in the AWS documentation.

## Cloudera Director

An application for deploying and managing CDH clusters using configuration template files.

## Cloudera Manager

An end-to-end management application for CDH clusters. Cloudera Manager enables administrators to easily and effectively provision, monitor, and manage Hadoop clusters and CDH installations.

## cluster

A set of computers that contains an HDFS file system and other CDH components.

## cluster launcher

An instance that launches a cluster using Cloudera Director and the configuration file.

# configuration file

A template file used by Cloudera Director that you modify to launch a CDH cluster.

# deployment

See cluster. Additionally, deployment refers to the process of launching a cluster.

## environment

The region, account credentials, and other information used to deploy clusters in a cloud infrastructure provider.

## transient cluster

A short lived cluster that launches, processes a set of data, and terminates. Transient clusters are ideal for periodic jobs.

## instance

One virtual server running in a cloud environment, such as AWS.

## instance group

A specification that includes general instance settings (such as the instance type and role settings), which you can use to launch instances without specifying settings for each individual instance.

## instance type

A specification that defines the memory, CPU, storage capacity, and hourly cost for an instance.

## keys

The combination of your AWS access key ID and secret access key used to sign AWS requests.

## long-lived cluster

A cluster that remains running and available.

## provider

A company that offers a cloud infrastructure which includes computing, storage, and platform services. Amazon Web Services (AWS), Google Cloud Platform, and Microsoft Azure are cloud providers.

## region

A distinct geographical AWS data center location. Each region contains at least two availability zones. For a list of regions and availability zones, see

http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-regions-availability-zones.html.

## tags

Metadata (name/value pairs) that you can define and assign to instances. Tags make is easier to find instances using environment management tools. For example, AWS provides the AWS Management Console.

# template

A template file that contains settings that you use to launch clusters.

### TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

#### 1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

## 2. Grant of Copyright License.

Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

#### 3. Grant of Patent License.

Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims

licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

#### 4. Redistribution.

You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

- 1. You must give any other recipients of the Work or Derivative Works a copy of this License; and
- 2. You must cause any modified files to carry prominent notices stating that You changed the files; and
- **3.** You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
- **4.** If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

### 5. Submission of Contributions.

Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

#### 6. Trademarks.

This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

## 7. Disclaimer of Warranty.

Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

### 8. Limitation of Liability.

In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

## 9. Accepting Warranty or Additional Liability.

## Appendix: Apache License, Version 2.0

While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

#### **END OF TERMS AND CONDITIONS**

### APPENDIX: How to apply the Apache License to your work

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "[]" replaced with your own identifying information. (Don't include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.
