Audit Overview

Apache Ranger provides a centralized framework for collecting access audit history and reporting data, including filtering on various parameters. Ranger enhances audit information obtained from Hadoop components and provides insights through this centralized reporting capability.

Managing Auditing with Ranger

To explore options for auditing policies in Ranger, click Audit in the top menu.

Policy ID	Policy Version	Event Time	Application	User	Service Name / Type	Resource Name / Type	Access Type	Result	Access Enforcer	Agent Host Name	Client IP	C
3	1	07/21/2019 12:21:35 PM	hbaseMaster	hbase	cm_hbase	hbase	balance	Allowed	ranger-acl	dhoyle-7-1-1.vpc.cloudera.com		C
3	1	07/21/2019 12:16:30 PM	hbaseMaster	hbase	cm_hbase	hbase	balance	Allowed	ranger-acl	dhoyle-7-1-1.vpc.cloudera.com		C

Audit > User Sync: Sync details

The screenshot shows the Ranger web interface with the 'User Sync' tab selected. A search bar at the top indicates 'START DATE: 07/21/2019'. Below the search bar, a status bar shows 'Entries: 1 to 25 of 803' and 'Last Updated Time: 07/21/2019 01:23:45 PM'. The main table displays sync events with columns for User Name, Sync Source, Number Of New Users/Groups, Number Of Modified Users/Groups, Event Time, and Sync Details. A blue box highlights the 'Sync Details' icon for the second entry, which is linked to a modal window titled 'Sync Details'.

User Name	Sync Source	Number Of New		Number Of Modified		Event Time	Sync Details
		Users	Groups	Users	Groups		
rangerusersync	Unix	0	0	0	0	07/21/2019 01:22:48 PM	[Icon]

Create a read-only Admin user (Auditor)

Creating a read-only Admin user (Auditor) enables compliance activities because this user can monitor policies and audit events, but cannot make changes.

About this task

When a user with the Auditor role logs in, they see a read-only view of Ranger policies and audit events. An Auditor can search and filter on access audit events, and access and view all tabs under Audit to understand access events. They cannot edit users or groups, export/import policies, or make changes of any kind.

Procedure

1. Select Settings > Users/Groups/Roles.
2. Click Add New User.

3. Complete the **User Detail** section, selecting Auditor as the role:

The screenshot shows the Ranger 'User Create' interface. The 'User Detail' section is active. The 'User Name' field is filled with 'auditor1'. The 'New Password' and 'Password Confirm' fields are masked with dots. The 'First Name' field is filled with 'Audrey'. The 'Last Name' field is empty. The 'Email Address' field is empty. The 'Select Role' dropdown menu is open, showing 'Auditor' as the selected option. The 'Group' field is filled with 'audit'. At the bottom, there are 'Save' and 'Cancel' buttons.

4. Click Save.

Update Ranger audit configuration parameters

How to change the default time settings that control how long Ranger keeps audit data collected by solr.

About this task

You can configure parameters that control how much data collected by solr that Ranger will store for auditing purposes.

Table 1: Ranger Audit Configuration Parameters

Parameter Name	Description	Default Setting	Units
ranger.audit.solr.config.ttl	Time To Live for Solr Collection of Ranger Audits	90	days
ranger.audit.solr.config.delete.trigger	Auto Delete Period in seconds for Solr Collection of Ranger Audits for expired documents	1	days (configurable)

Note: "Time To Live for Solr Collection of Ranger Audits" is also known as the Max Retention Days attribute.

Procedure

1. From Cloudera Manager choose Ranger Configuration .
2. In Search, type ranger.audit.solr.config, then press Return.
3. In ranger.audit.solr.config.ttl, set the the number of days to keep audit data.
4. In ranger.audit.solr.config.delete.trigger set the number and units (days, minutes, hours, or seconds) to keep data for expired documents

5. Refresh the configuration, using one of the following two options:
 - a) Click Refresh Configuration, as prompted or, if Refresh Configuration does not appear,
 - b) In Actions, click Update Solr config-set for Ranger, then confirm.

How to trigger HDFS audit files rollover

How to configure when HDFS audit files close for each service.

About this task

By default, the Ranger Audit framework closes audit files created in HDFS or other cloud storage inline with audit event triggers. In other words, when an audit event occurs, Ranger checks the configured rollout time and then closes the file if the threshold has reached. Default audit rollout time is 24 hours. If no audit event occurs in a 24 hour period, files remain open beyond the 24 hour period. In some environments, audit log analysis that encounter an audit file open beyond the current date can cause system exceptions. If you want the files to be closed every day, so that the audit log file will have only that day's log and the next day's log will be in the next day's file, you can configure the audit framework to close files every day. To do this, you must add several configuration parameters to the ranger-`<service_name>-audit.xml` (safety valve) file for each service, using Cloudera Manager.

Procedure

1. From Cloudera Manager choose `<service_name>` Configuration .
2. In `<service_name>` Configuration Search , type `ranger-<service_name>`, then press Return.
3. In `<service_name>` Server Advanced Configuration Snippet (Safety Valve) for `ranger-<service_name>-audit.xml`, do the following steps:
 - a) Click + (Add).
 - b) In Name, type `xasecure.audit.destination.hdfs.file.rollover.enable.periodic.rollover`
 - c) In Value, type `true`.

When this is enabled Ranger Audit Framework will spawn a Scheduler thread which monitors the occurrence of closing threshold and closes the file. By default every night the file gets closed.

- d) Click + (Add another).
- e) In Name, type `xasecure.audit.destination.hdfs.file.rollover.sec`
- f) In Value, type an integer value in seconds.

This is the time in seconds when the file has to be closed. The default value is 86400 sec (1 day) which triggers the file to be closed at midnight and opens a new audit log for the next day. You can override the default value

can be overridden by setting this parameter. For example, if you set the value 3600 (1 hr), the file gets closed every hour.

- g) Click + (Add another).
- h) In Name, type `xasecure.audit.destination.hdfs.file.rollover.periodic.rollover.check.sec`
- i) In Value, type an integer value in seconds.

This is the time frequency of the check to be done whether the threshold time for rollover has occurred. By default the check is done every 60 secs. You can configure this parameter to delay the check time.

Figure 1: Example: Hive service configured to trigger rollover of hdfs audit files

The screenshot shows the Cloudera Ranger Admin web UI for the 'HIVE-1' service. The 'Configuration' tab is selected, showing a configuration snippet titled 'Hive Service Advanced Configuration Snippet (Safety Valve) for ranger-hive-audit.xml'. On the left, there are filters for SCOPE (HIVE-1 (Service-Wide) with 3 items) and CATEGORY (Main with 0 items, Advanced with 3 items, etc.). The main area displays three configuration items:

- Name:** `xasecure.audit.destination.hdfs.file.rollover.enable.periodic.rollover`
Value: `true`
- Name:** `xasecure.audit.destination.hdfs.file.rollover.sec`
Value: `3600`
- Name:** `xasecure.audit.destination.hdfs.file.rollover.periodic.rollover.check.sec`
Value: `3600`

At the bottom, a status bar shows '1 Edited Value' and a 'Save Changes(CTRL+S)' button.

- j) Click Save Changes (CTRL+S).
- 4. Repeat steps 1-3 for each service.
- 5. Restart the service.

Ranger Audit Filters

You can use Ranger audit filters to control the amount of audit log data collected and stored on your cluster.

About Ranger audit filters

Ranger audit filters allow you to control the amount of audit log data for each Ranger service. Audit filters are defined using a JSON string that is added to each service configuration. The audit filter JSON string is a simplified form of the Ranger policy JSON. Audit filters appear as rows in the Audit Filter section of the Edit Service view for each service. The set of audit filter rows defines the audit log policy for the service. For example, the default audit log policy for the Hadoop SQL service appears in the in the Ranger Admin web UI Service Manager Edit Service when you scroll down to Audit Filter. Audit filter is checked (visible) by default. In this example, the top row defines an audit filter that causes all instances of "access denied" to appear in audit logs. The lower row defines a filter that

Default audit filter policies do not exist for Yarn, NiFi, NiFi Registry, Kudu, or schema registry services.

Ranger audit filter policy configuration

To configure an audit filter policy, click the Edit icon for either a resource-, or tag-based service in the Ranger Admin web UI. You configure a Ranger audit filter policy by adding (+), deleting (X), or modifying each audit filter row for the service. The preceding example shows the Add and Delete icons for each filter row. To configure each filter in the policy, use the controls in the filter row to edit filter properties. For example, you can configure:

Is Audited: choose Yes or No

to include or not include a filter in the audit logs for a service

Access Result: choose DENIED, ALLOWED, or NOT_DETERMINED

to include that access result in the audit log filter

Resources: Add or Delete a resource item

to include or remove the resource from the audit log filter

Operations: Add or Remove an action name

to include the action/operation in the audit log filter

(click x to remove an existing operation)

Permissions: Add or Remove permissions

1. Click + in Permissions to open the Add dialog.
2. Select/Unselect required permissions.

For example, in HDFS service select read, write, execute, or All permissions.

Users: click Select User to see a list of defined users

to include one or multiple users in the audit log filter

Groups: click Select Group to see a list of defined groups

to include one or multiple groups in the audit log filter

Roles: click Select Role to see a list of defined roles

to include one or multiple roles in the audit log filter

Audit filter details

- When you save the UI selections described in the preceding list, audit filters are defined as a JSON list. Each service references a unique list.
- For example, ranger.plugin.audit.filters for the HDFS service includes:

```
[
  {
    "accessResult": "DENIED",
    "isAudited": true
  },
  {
    "users": [
      "unaudited-user1"
    ],
    "groups": [
      "unaudited-group1"
    ],
    "roles": [
      "unaudited-role1"
    ]
  }
]
```

```

    ],
    "isAudited":false
  },
  {
    "actions":[
      "listStatus",
      "getFileinfo"
    ],
    "accessTypes":[
      "execute"
    ],
    "isAudited":false
  },
  {
    "resources":{
      "path":{
        "values":[
          "/audited"
        ],
        "isRecursive":true
      }
    },
    "isAudited":true
  },
  {
    "resources":{
      "path":{
        "values":[
          "/unaudited"
        ],
        "isRecursive":true
      }
    },
    "isAudited":false
  }
]

```

- Each value in the list is an audit filter, which takes the format of a simplified Ranger policy, along with access results fields.
- Audit filters are defined with rules on Ranger policy attributes and access result attributes.
 - Policy attributes: resources, users, groups, roles, accessTypes
 - Access result attributes: isAudited, actions, accessResult
- The following audit filter specifies that accessResult=DENIED will be audited.

The isAudited flag specifies whether or not to audit.

```
{ "accessResult": "DENIED", "isAudited": true }
```

- The following audit filter specifies that “resource => /unaudited” will not be audited.

```
{ "resources": { "path": { "values": [ "/unaudited" ], "isRecursive": true } }, "isAudited": false }
```

- The following audit filter specifies that access to resource database=> sys table=> dump by user “use2” will not be audited.

```
{ "resources": { "database": { "values": [ "sys" ] }, "table": { "values": [ "dump" ] } }, "users": [ "user2" ], "isAudited": false }
```

- The following audit filter specifies that access result in actions => listStatus, getFileInfo and accessType => execute will not be audited.

```
{ "actions": [ "listStatus", "getFileinfo" ], "accessTypes": [ "execute" ], "isAudited": false }
```

- The following audit filter specifies that access by user "superuser1" and group "supergroup1" will not be audited.

```
{"users":["superuser1"],"groups":["supergroup1"],"isAudited":false}
```

- The following audit filter specifies that access to any resource tagged as NO_AUDIT will not be audited.

```
{"resources":{"tag":{"values":["NO_AUDIT"]}},"isAudited":false}
```

Changing Ranger audit storage location and migrating data

How to change the location of existing and future Ranger audit data collected by Solr from HDFS to a local file system or from a local file system to HDFS.

Before you begin

- Stop Atlas from Cloudera Manager.
- If using Kerberos, set the SOLR_PROCESS_DIR environment variable.

```
# export SOLR_PROCESS_DIR=$(ls -ldtr /var/run/cloudera-scm-agent/process/  
*SOLR_SERVER | tail -1)
```

About this task

Starting with Cloudera Runtime version 7.1.4 / 7.2.2, the storage location for ranger audit data collected by Solr changed to local file system from HDFS, as was true for previous versions. The default storage location Ranger audit data storage location for Cloudera Runtime-7.1.4+ and Cloudera Runtime-7.2.2+ installations is local file system. After upgrading from an earlier Cloudera platform version, follow these steps to backup and migrate your Ranger audit data and change the location where Solr stores your future Ranger audit records.

- The default value of the index storage in the local file system is /var/lib/solr-infra. You can configure this, using Cloudera Manager Solr Configuration "Solr Data Directory" .
- The default value of the index storage in HDFS is /solr-infra. You can configure this, using Cloudera Manager Solr Configuration "HDFS Data Directory" .

Procedure

1. Create HDFS Directory to store the collection backups.

As an HDFS super user, run the following commands to create the backup directory:

```
# hdfs dfs -mkdir /solr-backups  
# hdfs dfs -chown solr:solr /solr-backups
```

2. Obtain valid kerberos ticket for Solr user.

```
# kinit -kt solr.keytab solr/$(hostname -f)
```

3. Download the configs for the collection.

```
# solrctl instancedir --get ranger_audits /tmp/ranger_audits  
# solrctl instancedir --get atlas_configs /tmp/atlas_configs
```

4. Modify the solrconfig.xml for each of the configs for which data needs to be stored in HDFS.

In /tmp/<config_name>/conf created during Step 3., edit properties in the solrconfig.xml file as follows:

- When migrating your data storage location from a local file system to HDFS, replace these two lines:

```
<directoryFactory name="DirectoryFactory"  
class="${solr.directoryFactory:solr.NRTCachingDirectoryFactory}">
```

```
<lockType>${solr.lock.type:native}</lockType>
```

with

```
<directoryFactory name="DirectoryFactory"
  class="${solr.directoryFactory:org.apache.solr.core.HdfsDirectoryFactory}">
<lockType>${solr.lock.type:hdfs}</lockType>
```

- When migrating your data storage location from HDFS to a local file system, replace these two lines:

```
<directoryFactory name="DirectoryFactory"
  class="${solr.directoryFactory:org.apache.solr.core.HdfsDirectoryFactory}">
<lockType>${solr.lock.type:hdfs}</lockType>
```

with

```
<directoryFactory name="DirectoryFactory"
  class="${solr.directoryFactory:solr.NRTCachingDirectoryFactory}">
<lockType>${solr.lock.type:native}</lockType>
```

5. Update the modified configs in Zookeeper.

```
# solrctl --jaas $SOLR_PROCESS_DIR/jaas.conf instancedir --update
  atlas_configs /tmp/atlas_configs
# solrctl --jaas $SOLR_PROCESS_DIR/jaas.conf instancedir --update
  ranger_audits /tmp/ranger_audits
```

6. Backup the Solr collections.

- When migrating your data storage location from a local file system to HDFS, run:

```
# curl -k --negotiate -u : "https://$(hostname
-f):8995/solr/admin/collections?action=BACKUP&name=vertex_backup&col
lection=vertex_index&
location=hdfs://<Namenode_Hostname>:8020/solr-backups"
```

In the preceding command, the important points are name, collection, and location:

name

specifies the name of the backup. It should be unique per collection

collection

specifies the collection name for which the backup will be performed

location

specifies the HDFS path, where the backup will be stored

Repeat the curl command for different collections, modifying the parameters as necessary for each collection.

The expected output would be -

```
"responseHeader":{
  "status":0,
  "QTime":10567},
"success":{
  "Solr_Server_Hostname:8995_solr":{
    "responseHeader":{
      "status":0,
```

```
"QTime":8959}}}}
```

- When migrating your data storage location from HDFS to a local file system:

Refer to Back up a Solr collection for specific steps, and make the following adjustments:

- If TLS is enabled for the Solr service, specify the trust store and password by using the ZKCLI_JVM_FLAGS environment variable before you begin the procedure.

```
# export ZKCLI_JVM_FLAGS="-Djavax.net.ssl.trustStore=/path/to/truststore.jks -Djavax.net.ssl.trustStorePassword="
```

- Create Snapshot

```
# solrctl --jaas $SOLR_PROCESS_DIR/jaas.conf collection --create-snapshot <snapshot_name> -c <collection_name>
```

- or use the Solr API to take the backup:

```
curl -i -k --negotiate -u : "https://(hostname -f):8995/solr/admin/collections?action=BACKUP&name=ranger_audits_bkp&collection=ranger_audits&location=/path/to/solr-backups"
```

- Export Snapshot

```
# solrctl --jaas $SOLR_PROCESS_DIR/jaas.conf collection --export-snapshot <snapshot_name> -c <collection_name> -d <destination_directory>
```

Note: The <destination_directory> is a HDFS path. The ownership of this directory should be solr:solr.

7. Delete the collections from the original location.

All instances of Solr service should be up, running, and healthy before deleting the collections. Use Cloudera Manager to check for any alerts or warnings for any of the instances. If alerts or warnings exist, fix those before deleting the collection.

```
# solrctl collection --delete edge_index
# solrctl collection --delete vertex_index
# solrctl collection --delete fulltext_index
# solrctl collection --delete ranger_audits
```

8. Verify that the collections are deleted from the original location.

```
# solrctl collection --list
```

This will give an empty result.

9. Verify that no leftover directories for any of the collections have been deleted.

- When migrating your data storage location from a local file system to HDFS:

```
# cd /var/lib/solr-infra
```

Get the value of "Solr Data Directory, using Cloudera Manager Solr Configuration .

```
# ls -ltr
```

- When migrating your data storage location from HDFS to a local file system, replace these two lines:

```
# hdfs dfs -ls /solr/<collection_name>
```

Note: If any directory name which starts with the collection name deleted in Step 7. exists, delete/ move the directory to another path.

10. Restore the collection from backup to the new location.

Refer to [Restore a Solr collection](#), for more specific steps.

```
# curl -k --negotiate -u : "https://$(hostname -f):8995/solr/admin/collections?
action=RESTORE&name=<Name_of_backup>&location=hdfs:/
<Namenode_Hostname>:8020/solr-backups&collection=<Collection_Name>"
```

```
# solrctl collection --restore ranger_audits
-l hdfs://<Namenode_Hostname>:8020/solr-backups
-b ranger_backup -i ranger1
```

The request id must be unique for each restore operation, as well as for each retry.

To check the status of restore operation:

```
# solrctl collection --request-status <requestId>
```

Note: If the Atlas Collections (vertex_index, fulltext_index and edge_index) restore operations fail, restart the solr service and rerun the restore command. Now, the restart operations should complete successfully.

11. Verify the Atlas & Ranger functionality.

Verify that both Atlas and Ranger audits functions properly, and that you can see the latest audits in Ranger Web UI and latest lineage in Atlas.

- To verify Atlas audits, create a test table in Hive, and then query the collections to see if you are able to view the data.
- You can also query the collections every 20-30 seconds (depending on how other services utilize Atlas/Ranger), and verify if the "numDocs" value increases at every query.

```
# curl -k --negotiate -u : "https://$(hostname -f):8995/solr/edge_index/
select?q=%3A*&wt=json&ident=true&rows=0"
# curl -k --negotiate -u : "https://$(hostname -f):8995/solr/vertex_index/
select?q=%3A*&wt=json&ident=true&rows=0"
# curl -k --negotiate -u : "https://$(hostname -f):8995/solr/
fulltext_index/select?q=%3A*&wt=json&ident=true&rows=0"
# curl -k --negotiate -u : "https://$(hostname -f):8995/solr/
ranger_audits/select?q=%3A*&wt=json&ident=true&rows=0"
```
