Contents

Cloudera Search security aspects

Cloudera Search security covers the following security aspects:

- Securing network communication

  Cloudera Search supports TLS for encrypting communications over a network.
- Authentication

  Cloudera Search supports Kerberos and LDAP for authentication.
- Authorization

  Cloudera Search supports Apache Ranger for authorization.

Related Tasks

Configuring Ranger authorization for Solr in a DDE Data Hub cluster

Enabling ZooKeeper SSL/TLS for Solr and HBase Indexer

Learn about configuring Solr and HBase Indexer to communicate with ZooKeeper in a secure way.

Important: The options described here may already be visible in CDP version 7.2.17, but do not turn them on if your CDP is not at least version 7.2.17.300 or higher.

Related Information

Configure ZooKeeper TLS/SSL using Cloudera Manager

Enabling SSL for Solr ZooKeeper

Learn about enabling secure communications between Solr and ZooKeeper.

Before you begin

- The Enable TLS/SSL for ZooKeeper and Client Port Unification options must be enabled in the ZooKeeper configuration (These are the default settings for a secure cluster).

Procedure

1. In Cloudera Manager, select the Solr service for which you want to enable secure communication.
2. Click the Configuration tab.
3. Search for SSL.
4. Find the Enable TLS/SSL for Solr ZooKeeper property and select it to enable TLS/SSL.
5. Click Save Changes.
6. Restart.

Enabling SSL for HBase Indexer ZooKeeper

Learn about enabling secure communication between HBase Indexer and ZooKeeper.

Before you begin

- The Enable TLS/SSL for ZooKeeper and Client Port Unification options must be selected in the ZooKeeper configuration (These are the default settings for a secure cluster).
- The Enable TLS/SSL for Solr Zookeeper must be selected for the Solr service used with HBase Indexer. When you disable SSL/TLS for HBase indexer ZooKeepeer, make sure that you disable it for the Solr service as well.

Procedure

1. In Cloudera Manager, select the HBase service for which you want to enable secure communication.
2. Click the Configuration tab.
3. Search for SSL.
4. Find the Enable TLS/SSL for HBase ZooKeeper property and select it to enable TLS/SSL.
5. Click Save Changes.
6. Restart.

Enable LDAP authentication in Solr

You can configure LDAP-based authentication using Cloudera Manager at the Solr service level.

Before you begin

Note: Depending on how your environment is set up, you may have issues with DNS resolution. You can avoid it by using IP addresses instead of hostnames.

About this task

Solr supports LDAP authentication for external Solr clients including:

- Command-line tools
- curl
- Web browsers
- Solr Java clients

In some cases, Solr does not support LDAP authentication. Use Kerberos authentication instead in these cases. Solr does not support LDAP authentication with:

- Search indexing components including the MapReduce indexer and Lily HBase indexer.
- Solr internal requests such as those for replication or querying.
- Hadoop delegation token management requests such as GETDELEGATIONTOKEN or RENEWDELEGAT IONTOKEN.

Before you begin

- Configuring LDAP authentication requires that Kerberos authentication is already configured and enabled in Solr.
- For secure LDAP connections, it is a prerequisite that TLS/SSL has been configured and enabled in Solr.

Procedure

1. In Cloudera Manager select the Solr service.
2. Click the Configuration tab.
3. Select Scope Solr .
4. Select Category Security .
5. Select Enable LDAP Authentication.

6. Enter the LDAP URL in the LDAP URL property.

   To configure a TLS encrypted LDAP connection, select one of the following options:

   - ldaps://<*ldap_server*>:<*port*>

     The default port is 636.

   OR

   - ldap://<*ldap_server*>:<*port*>

     The default port is 389.

     Select Enable LDAP TLS. This is not required when using an LDAP URL with prefix ldaps://, because that already specifies TLS.

   To configure LDAP with unencrypted transmission of usernames and passwords, set ldap://<ldap_server>:<port>, without setting Enable LDAP TLS.
7. Configure only one of following mutually exclusive parameters:
   - LDAP BaseDN: Replaces the username with a "distinguished name" (DN) of the form: uid=userid,ldap_base DN. Typically used for OpenLDAP server installation.
   - Active Directory Domain: Replaces the username with a string username@ldap_domain. Typically used for Active Directory server installation.
8. Launch the Stale Configuration wizard to restart the Solr service and any dependent services.

Creating a JAAS configuration file

Certain applications, such as those using the SolrJ library, require a Java Authentication and Authorization Service (JAAS) configuration file.

- If you are authenticating using kinit to obtain credentials, you can configure the client to use your credentials cache by creating a JAAS file with the following contents:

```
Client {
 com.sun.security.auth.module.Krb5LoginModule required
 useKeyTab=false
 useTicketCache=true
 principal="[***USER***]@[***REALM***]";
 };
```

- If you want the client application to authenticate using a keytab, create a JAAS file with the following contents:

```
Client {
 com.sun.security.auth.module.Krb5LoginModule required
 useKeyTab=true
 keyTab="[***PATH/TO/USER.KEYTAB***]"
 storeKey=true
 useTicketCache=false
 principal="[***USER***]/[***HOST NAME***]@[***REALM***]";
};
```

[USER***]***

is a valid user name in your environment

/[HOST NAME***]***

If you use a service principal that includes the host name, make sure that it is included in the jaas .conf file (for example, solr/solr01.example.com@EXAMPLE.COM).

[REALM***]***

is your Kerberos realm

[PATH/TO/USER.KEYTAB***]***

is the path to the keytab file you want to use

Manage Ranger authorization in Solr

Using Cloudera Manager, you can turn on and off Ranger authorization for your Solr service.

About this task

Ranger restrictions are consistently applied regardless of the way users attempt to complete actions. For example, restricting access to data in a collection consistently restricts that access, whether queries come from the command line, from a browser, or through the admin console.

Procedure

1. In Cloudera Manager select the Solr service.
2. Select Configuration and find the RANGER Service property.
3. To turn on Ranger authorization, select the Ranger service that you want the Solr service to depend on. To turn off Ranger authorization, unselect the Ranger service.
4. Click Save Changes.
5. Restart the Solr service.

Results

Ranger authorization for Solr is enabled. The Solr service depends on the selected Ranger service for authorization.

Configuring Ranger authorization for Solr in a DDE Data Hub cluster

By default, the Solr service deployed with a Data Discovery and Experience (DDE) cluster is not configured for authorization by Ranger. You can configure authorization manually, using Cloudera Management Console.

Before you begin

Minimum Required Role: environmentAdmin

Procedure

1. Navigate to the Ranger service of the data lake where DDE is running.
2. On the **Service Manager** page, click the Add icon next to Solr.
3. Enter the following information on the **Create Service** page:

   Service Details

Field name	Description
Service Name	Assign a name to the Solr service you want to create. Note down the value you define here. You need to enter it later, when specifying the ranger.plugin.solr.service.name parameter in the Solr Service Advanced Configuration Snippet (Safety Valve) for ranger-solr-security.xml option.

Field name	Description
Active Status	Enabled
Select Tag Service	Select cm_tag.

Configuration Properties

Field name	Description
Username	Assign a placeholder value. This property is not used in case of Kerberos authentication.
Password	Assign a placeholder value. This property is not used in case of Kerberos authentication.
Solr URL	Assign a placeholder value. This property is not used in case of Kerberos authentication.
Add new configurations	Add the following new configurations: • policy.download.auth.users = solr • tag.download.auth.users = solr

Note:

Do not click Test connection. In this use case it is not necessary and it does not work.

4. Click Save.
5. Click on the newly added service.
   The **List of Policies** page opens.
6. Under Action click the Edit icon.
7. In Allow Conditions Select User dropdown select hue.

   This is necessary because the Hue service breaks if it has no permission to access Solr.

   To keep the cluster accessible to non-admin users, you can add other users to the default policy or you can define additional policies.
8. Grant full admin privileges to users that you want to be able to access the Solr Admin UI.
   a) Click Add under Allow Conditions to add a new condition, then add the user or users from the Select User drop-down.
   b) Click Add Permissions then select the Select/Deselect All option.
   c) Accept the selection, then click Save.
9. Navigate to the Cloudera Manager (CM) UI on the DDE cluster.
10. From Clusters select Solr.
11. Select the **Configuration** tab.
12. In the Search field start typing ‘safety’
13. Click Add under Solr Service Advanced Configuration Snippet (Safety Valve).
14. Define the following:

    Key

    ranger.plugin.solr.service.name

    Value

    The Solr Service Name you assigned when creating the Solr service in Ranger.
15. Click Save Changes.
16. Click the Status tab to refresh the window.
17. Click the Stale Configuration: Restart needed indicator on top of the page.
18. Click Restart Stale Services.
19. Click Restart Now.

Enable Ranger document-level authorization for a Solr collection

By default, Ranger authorization works on collection level. Ranger allows you to configure document level security for individual Solr collections. This requires updating the solrconfig.xml file belonging to the particular collection. For the authorization to work on existing collections, you need to update the collection as well, by adding the rang er_auth parameter with an appropriate value to individual documents.

Important:

Document-level authorization does not prevent users from modifying documents or performing other update operations on the collection. Update operations are only governed by collection-level authorization.

Document-level authorization can exclusively be used to prevent documents being returned in query results. If users are not granted access to a document, those documents are not returned even if that user submits a query that matches those documents. This does not affect attempted updates.

Consequently, it is possible for a user to not have access to a set of documents based on document-level security, but to still be able to modify the documents using their collection-level authorization update rights. This means that a user can delete all documents in the collection. Similarly, a user might modify all documents, adding their authorization token to each one. After such a modification, the user could access any document using querying.

Therefore, if you restrict access using document-level security, consider granting collection-level update rights only to those users you trust and assume they will be able to access every document in the collection.

Prerequisites

1. Define or edit roles on Ranger UI and assign them to users/groups.
2. Create a new collection configuration or download an existing one for editing.

Enabling document-level authorization

1. Add ranger_auth field to the schema file and add hooks to solrconfig.xml that trigger document-level authorization.
2. Disable Ranger authorization.
3. Upload the configuration to ZooKeeper.
4. If you updated an existing collection to enable document-level authorization, add appropriate values to the newly created ranger_auth field before you turn on Ranger authorization. For example, you can reindex your collection, using one of the batch-indexing options offered by Cloudera Search.
5. To take document-level authorization into use, create a collection using the updated configuration (new collections) or reload your collection (updating an existing collection).
6. Enable Ranger authorization.

Modify the schema and solrconfig files to enable document-level authorization

To enable document-level Ranger authorization, you need to add a field in the schema file determining the roles that can access a particular document in the collection. You also need to edit the solrconfig file to include the hooks that trigger Ranger document level authorization based on the schema field values.

Before you begin

1. Disable Ranger authorization.

2. Define or edit roles on Ranger UI and assign them to users/groups.
3. Create a new collection configuration or download an existing one for editing.

Procedure

1. If you are using Kerberos, kinit as a user with sufficient rights to create or modify collections:

```
kinit [***KERBEROS PRINCIPAL***]@[***EXAMPLE.COM***]
```

   Replace *[***KERBEROS PRINCIPAL***]@[***EXAMPLE.COM***]* with your Kerberos principal and your Kerberos realm name respectively.

2. Go to the conf subdirectory of the newly created/downloaded folder to edit the schema file. (In our example it is mycollection/conf)

   The file name is either managed-schema or schema.xml based on the schema factory used.

3. Add a field that determines which roles have access to a particular document. In this example we name this field ranger_auth.

   Add the following to the list of fields in your schema, making sure the value of the type property is string; the values of the indexed, stored, and multiValued properties are true:

```
<field name="ranger_auth" type="string" indexed="true" stored="true" re
quired="false" multiValued="true"/>
```

4. Open the solrconfig.xml file for editing
5. Locate the section which contains the list of search components. In the default configuration it starts with a comment block similar to this:

```
<!-- Search Components
       Search components are registered to SolrCore and used by
       instances of SearchHandler (which can access them by name)
       ...
  -->
```

6. Add a new SearchComponent:

```
<searchComponent name="queryDocAuthorization" class="org.apache.ranger.a
uthorization.solr.authorizer.RangerSolrAuthorizer">
    <str name="enabled">true</str>
    <!-- The field which contains the role or list of roles which are all
owed to query a particular document -->
    <str name="rangerAuthField">ranger_auth</str>
    <!-- If the rangerAuthField contains this value, all roles will be all
owed to query that particular document -->
    <str name="allRolesToken">*</str>
 </searchComponent>
```

7. Add queryDocAuthorization to the first-components array of the /query, /get, /browse, /tvrh, /terms, and /elevate request handlers as well, in case they are present in your solrconfig.xml.

   Locate the request handler /select section:

```
<requestHandler name="/select" class="solr.SearchHandler">
    <!-- default values for query parameters can be specified, these
         will be overridden by parameters in the request
       -->
    <lst name="defaults">
      <str name="echoParams">explicit</str>
```

```
      <int name="rows">10</int>
```

To the end of this section, before the closing tag, insert queryDocAuthorization to the first-components array:

```
<arr name="first-components">
       <str>queryDocAuthorization</str>
     </arr>
  </requestHandler>
```

Note: /get (real-time get request handler) is implicitly defined even if it does not appear in solrconfig.xml. In case of using document level security, Cloudera recommends to also protect the /get handler. To do that, you need to explicitly add it to the solrconfig.xml and define queryDocAuthorization as a first-co mponent:

```
<requestHandler name="/get" class="solr.RealTimeGetHandler">
  <lst name="defaults">
    <str name="omitHeader">true</str>
    <str name="wt">json</str>
    <str name="indent">true</str>
  </lst>
 <arr name="first-components">
       <str>queryDocAuthorization</str>
     </arr>
</requestHandler>
```

8. Locate the requestParsers section:

```
<requestParsers enableRemoteStreaming="true"
                   multipartUploadLimitInKB="2048000"
                   ...
                   />
```

Ensure that this section has a boolean attribute called addHttpRequestToContext with a value of true:

```
<requestParsers enableRemoteStreaming="true"
                   multipartUploadLimitInKB="2048000"
                   formdataUploadLimitInKB="2048"
                   addHttpRequestToContext="true"/>
```

What to do next

1. Upload the configuration metadata to ZooKeeper.
2. Populate the ranger_auth field for each document with roles you have defined in Ranger.
3. Create a new collection using the the updated configuration metadata, or update the configuration of an existing collection.
4. Enable Ranger authorization.

<!--
     For more details about configurations options that may appear in
     this file, see http://wiki.apache.org/solr/SolrConfigXml.
-->
<config>
  <!-- In all configuration below, a prefix of "solr." for class names
       is an alias that causes solr to search appropriate packages,
       including org.apache.solr.(search|update|request|core|analysis)

       You may also specify a fully qualified Java classname if you
       have your own custom plugins.
    -->
  <!-- Controls what version of Lucene various components of Solr
       adhere to.  Generally, you want to use the latest version to
       get all bug fixes and improvements. It is highly recommended
       that you fully re-index after changing this setting as it can
       affect both how text is indexed and queried.
  -->
  <luceneMatchVersion>8.4.1</luceneMatchVersion>

  <!-- <lib/> directives can be used to instruct Solr to load any Jars
       identified and use them to resolve any "plugins" specified in
       your solrconfig.xml or schema.xml (ie: Analyzers, Request
       Handlers, etc...).

       All directories and paths are resolved relative to the
       instanceDir.

       Please note that <lib/> directives are processed in the order
       that they appear in your solrconfig.xml file, and are "stacked"
       on top of each other when building a ClassLoader - so if you have
       plugin jars with dependencies on other jars, the "lower level"
       dependency jars should be loaded first.

       If a "./lib" directory exists in your instanceDir, all files
       found in it are included as if you had used the following
       syntax...
              <lib dir="./lib" />
    -->

  <!-- A 'dir' option by itself adds any files found in the directory
       to the classpath, this is useful for including all jars in a
       directory.
       When a 'regex' is specified in addition to a 'dir', only the
       files in that directory which completely match the regex
       (anchored on both ends) will be included.

       If a 'dir' option (with or without a regex) is used and nothing
       is found that matches, a warning will be logged.
```

```
       The example below can be used to load a solr-contrib along
       with their external dependencies.
    -->
    <!-- <lib dir="${solr.install.dir:../../../..}/dist/" regex="solr-ltr-
\d.*\.jar" /> -->

  <!-- an exact 'path' can be used instead of a 'dir' to specify a
       specific jar file.  This will cause a serious error to be logged
       if it can't be loaded.
    -->
  <!--
     <lib path="../a-jar-that-does-not-exist.jar" />
  -->

  <!-- Data Directory

       Used to specify an alternate directory to hold all index data
       other than the default ./data under the Solr home.  If
       replication is in use, this should match the replication
       configuration.
    -->
  <dataDir>${solr.data.dir:}</dataDir>

  <!-- The DirectoryFactory to use for indexes.
       solr.StandardDirectoryFactory is filesystem
       based and tries to pick the best implementation for the current
       JVM and platform.  solr.NRTCachingDirectoryFactory, the default,
       wraps solr.StandardDirectoryFactory and caches small files in memory
       for better NRT performance.

       One can force a particular implementation via solr.MMapDirectoryFa
ctory,
       solr.NIOFSDirectoryFactory, or solr.SimpleFSDirectoryFactory.
       solr.RAMDirectoryFactory is memory based and not persistent.
    -->

 -->
  <indexConfig>
    <!-- maxFieldLength was removed in 4.0. To get similar behavior, include
 a
         LimitTokenCountFilterFactory in your fieldType definition. E.g.
     <filter class="solr.LimitTokenCountFilterFactory" maxTokenCount="10000
"/>
    -->
    <!-- Maximum time to wait for a write lock (ms) for an IndexWriter. Defa
ult: 1000 -->
    <!-- <writeLockTimeout>1000</writeLockTimeout>  -->

    <!-- Expert: Enabling compound file will use less files for the index,
         using fewer file descriptors on the expense of performance decrea
se.
         Default in Lucene is "true". Default in Solr is "false" (since 3.6)
 -->
    <!-- <useCompoundFile>false</useCompoundFile> -->

    <!-- ramBufferSizeMB sets the amount of RAM that may be used by Lucene
         indexing for buffering added documents and deletions before they
 are
```

```
         flushed to the Directory.
         maxBufferedDocs sets a limit on the number of documents buffered
         before flushing.
         If both ramBufferSizeMB and maxBufferedDocs is set, then
         Lucene will flush based on whichever limit is hit first.  -->
    <ramBufferSizeMB>128</ramBufferSizeMB>
    <!-- <maxBufferedDocs>1000</maxBufferedDocs> -->

    <!-- Expert: ramPerThreadHardLimitMB sets the maximum amount of RAM that
 can be consumed
         per thread before they are flushed. When limit is exceeded, this
 triggers a forced
         flush even if ramBufferSizeMB has not been exceeded.
         This is a safety limit to prevent Lucene's DocumentsWriterPerThread
 from address space
         exhaustion due to its internal 32 bit signed integer based memory
addressing.
         The specified value should be greater than 0 and less than 2048MB.
When not specified,
         Solr uses Lucene's default value 1945. -->
    <!-- <ramPerThreadHardLimitMB>1945</ramPerThreadHardLimitMB> -->

    <!-- Expert: Merge Policy
         The Merge Policy in Lucene controls how merging of segments is done
.
         The default since Solr/Lucene 3.3 is TieredMergePolicy.
         The default since Lucene 2.3 was the LogByteSizeMergePolicy,
         Even older versions of Lucene used LogDocMergePolicy.
      -->
    <!--
        <mergePolicyFactory class="org.apache.solr.index.TieredMergePolic
yFactory">
          <int name="maxMergeAtOnce">10</int>
          <int name="segmentsPerTier">10</int>

        </mergePolicyFactory>
      -->

    <!-- Expert: Merge Scheduler
         The Merge Scheduler in Lucene controls how merges are
         performed.  The ConcurrentMergeScheduler (Lucene 2.3 default)
         can perform merges in the background using separate threads.
         The SerialMergeScheduler (Lucene 2.2 default) does not.
     -->
    <!--
       <mergeScheduler class="org.apache.lucene.index.ConcurrentMergeSched
uler"/>
       -->

    <!-- LockFactory

         This option specifies which Lucene LockFactory implementation
         to use.

         single = SingleInstanceLockFactory - suggested for a
                  read-only index or when there is no possibility of
                  another process trying to modify the index.
         native = NativeFSLockFactory - uses OS native file locking.
                  Do not use when multiple solr webapps in the same
                  JVM are attempting to share a single index.
         simple = SimpleFSLockFactory  - uses a plain file for locking

         Defaults: 'native' is default for Solr3.6 and later, otherwise
                   'simple' is the default
```

```
       More details on the nuances of each LockFactory...
       http://wiki.apache.org/lucene-java/AvailableLockFactories
  -->
  <lockType>${solr.lock.type:hdfs}</lockType>

  <!-- Commit Deletion Policy
       Custom deletion policies can be specified here. The class must
       implement org.apache.lucene.index.IndexDeletionPolicy.

       The default Solr IndexDeletionPolicy implementation supports
       deleting index commit points on number of commits, age of
       commit point and optimized status.

       The latest commit point should always be preserved regardless
       of the criteria.
  -->
  <!--

  <!-- The default high-performance update handler -->
  <updateHandler class="solr.DirectUpdateHandler2">

    <!-- Enables a transaction log, used for real-time get, durability, and
         and solr cloud replica recovery.  The log can grow as big as
         uncommitted changes to the index, so use of a hard autoCommit
         is recommended (see below).
         "dir" - the target directory for transaction logs, defaults to the
                solr data directory.
         "numVersionBuckets" - sets the number of buckets used to keep
                track of max version values when checking for re-ordered
                updates; increase this value to reduce the cost of
                synchronizing access to version buckets during high-volume
                indexing, this requires 8 bytes (long) * numVersionBuckets
                of heap space per Solr core.
    -->
    <updateLog>
      <str name="dir">${solr.ulog.dir:}</str>
      <int name="tlogDfsReplication">${solr.ulog.tlogDfsReplication:3}</int>
      <int name="numVersionBuckets">${solr.ulog.numVersionBuckets:65536}</
int>
    </updateLog>

    <!-- AutoCommit
         Perform a hard commit automatically under certain conditions.
         Instead of enabling autoCommit, consider using "commitWithin"
         when adding documents.

         http://wiki.apache.org/solr/UpdateXmlMessages

         maxDocs - Maximum number of documents to add since the last
                   commit before automatically triggering a new commit.

         maxTime - Maximum amount of time in ms that is allowed to pass
                   since a document was added before automatically
                   triggering a new commit.
         openSearcher - if false, the commit causes recent index changes
           to be flushed to stable storage, but does not cause a new
           searcher to be opened to make those changes visible.

         If the updateLog is enabled, then it's highly recommended to
         have some sort of hard autoCommit to limit the log size.
      -->
    <autoCommit>
      <maxTime>${solr.autoCommit.maxTime:60000}</maxTime>
      <openSearcher>false</openSearcher>
    </autoCommit>
    <!-- softAutoCommit is like autoCommit except it causes a
         'soft' commit which only ensures that changes are visible
         but does not ensure that data is synced to disk.  This is
         faster and more near-realtime friendly than a hard commit.
      -->

    <autoSoftCommit>
      <maxTime>${solr.autoSoftCommit.maxTime:15000}</maxTime>
    </autoSoftCommit>

  </updateHandler>

  <!-- IndexReaderFactory

       Use the following format to specify a custom IndexReaderFactory,
       which allows for alternate IndexReader implementations.

       ** Experimental Feature **

       Please note - Using a custom IndexReaderFactory may prevent
       certain other features from working. The API to
       IndexReaderFactory may change without warning or may even be
       removed from future releases if the problems cannot be
       resolved.

       ** Features that may not work with custom IndexReaderFactory **
       The ReplicationHandler assumes a disk-resident index. Using a
       custom IndexReader implementation may cause incompatibility
       with ReplicationHandler and may cause replication to not work
       correctly. See SOLR-1366 for details.

    -->
  <!--
  <indexReaderFactory name="IndexReaderFactory" class="package.class">
    <str name="someArg">Some Value</str>
  </indexReaderFactory >
  -->

  <!-- ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
       Query section - these settings control query time things like caches
       ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
 -->
  <query>

    <!-- Maximum number of clauses allowed when parsing a boolean query stri
ng.
```

```
         This limit only impacts boolean queries specified by a user as part
 of a query string,
         and provides per-collection controls on how complex user specified
 boolean queries can
         be.  Query strings that specify more clauses then this will result
 in an error.

         If this per-collection limit is greater then the global `maxBoolea
nClauses` limit
         specified in `solr.xml`, it will have no effect, as that setting al
so limits the size
         of user specified boolean queries.
      -->
    <maxBooleanClauses>${solr.max.booleanClauses:1024}</maxBooleanClauses>
    <!-- Solr Internal Query Caches

         There are two implementations of cache available for Solr,
         LRUCache, based on a synchronized LinkedHashMap, and
         FastLRUCache, based on a ConcurrentHashMap.

         FastLRUCache has faster gets and slower puts in single
         threaded operation and thus is generally faster than LRUCache
         when the hit ratio of the cache is high (> 75%), and may be
         faster under other scenarios on multi-cpu systems.
    -->

    <!-- Filter Cache

         Cache used by SolrIndexSearcher for filters (DocSets),
         unordered sets of *all* documents that match a query.  When a
         new searcher is opened, its caches may be prepopulated or
         "autowarmed" using data from caches in the old searcher.
         autowarmCount is the number of items to prepopulate.  For
         LRUCache, the autowarmed items will be the most recently
         accessed items.
         Parameters:
           class - the SolrCache implementation LRUCache or
               (LRUCache or FastLRUCache)
           size - the maximum number of entries in the cache
           initialSize - the initial capacity (number of entries) of
               the cache.  (see java.util.HashMap)
           autowarmCount - the number of entries to prepopulate from
               and old cache.
           maxRamMB - the maximum amount of RAM (in MB) that this cache is a
llowed
                      to occupy. Note that when this option is specified,
 the size
                      and initialSize parameters are ignored.
      -->
    <filterCache class="solr.FastLRUCache"
                 size="512"
                 initialSize="512"
                 autowarmCount="0"/>

    <!-- Query Result Cache

         Caches results of searches - ordered lists of document ids
         (DocList) based on a query, a sort, and the range of documents r
equested.
         Additional supported parameter by LRUCache:
            maxRamMB - the maximum amount of RAM (in MB) that this cache is
 allowed
                       to occupy
      -->
```

```
    <queryResultCache class="solr.LRUCache"
                      size="512"
                      initialSize="512"
                      autowarmCount="0"/>

    <!-- Document Cache

         Caches Lucene Document objects (the stored fields for each
         document).  Since Lucene internal document ids are transient,
         this cache will not be autowarmed.
      -->
    <documentCache class="solr.LRUCache"
                   size="512"
                   initialSize="512"
                   autowarmCount="0"/>

    <!-- custom cache currently used by block join -->
    <cache name="perSegFilter"
           class="solr.search.LRUCache"
           size="10"
           initialSize="0"
           autowarmCount="10"
           regenerator="solr.NoOpRegenerator" />

    <!-- Field Value Cache

         Cache used to hold field values that are quickly accessible
         by document id.  The fieldValueCache is created by default
         even if not configured here.
      -->
    <!--
       <fieldValueCache class="solr.FastLRUCache"
                        size="512"
                        autowarmCount="128"
                        showItems="32" />
      -->

    <!-- Custom Cache
         Example of a generic cache.  These caches may be accessed by
         name through SolrIndexSearcher.getCache(),cacheLookup(), and
         cacheInsert().  The purpose is to enable easy caching of
         user/application level data.  The regenerator argument should
         be specified as an implementation of solr.CacheRegenerator
         if autowarming is desired.
      -->
    <!--
       <cache name="myUserCache"
              class="solr.LRUCache"
              size="4096"
              initialSize="1024"
              autowarmCount="1024"
              regenerator="com.mycompany.MyRegenerator"
              />
      -->

    <!-- Lazy Field Loading

         If true, stored fields that are not requested will be loaded
         lazily.  This can result in a significant speed improvement
         if the usual case is to not load all stored fields,
         especially if the skipped fields are large compressed text
         fields.
    -->
    <enableLazyFieldLoading>true</enableLazyFieldLoading>
```

```
    <!-- Use Filter For Sorted Query

         A possible optimization that attempts to use a filter to
         satisfy a search.  If the requested sort does not include
         score, then the filterCache will be checked for a filter
         matching the query. If found, the filter will be used as the
         source of document ids, and then the sort will be applied to
         that.

         For most situations, this will not be useful unless you
         frequently get the same search repeatedly with different sort
         options, and none of them ever use "score"
      -->
    <!--
       <useFilterForSortedQuery>true</useFilterForSortedQuery>
      -->

    <!-- Result Window Size
         An optimization for use with the queryResultCache.  When a search
         is requested, a superset of the requested number of document ids
         are collected.  For example, if a search for a particular query
         requests matching documents 10 through 19, and queryWindowSize is
 50,
         then documents 0 through 49 will be collected and cached.  Any fu
rther
         requests in that range can be satisfied via the cache.
      -->
    <queryResultWindowSize>20</queryResultWindowSize>

    <!-- Maximum number of documents to cache for any entry in the
         queryResultCache.
      -->
    <queryResultMaxDocsCached>200</queryResultMaxDocsCached>
    <!-- Query Related Event Listeners
         Various IndexSearcher related events can trigger Listeners to
         take actions.

         newSearcher - fired whenever a new searcher is being prepared
         and there is a current searcher handling requests (aka
         registered).  It can be used to prime certain caches to
         prevent long request times for certain requests.

         firstSearcher - fired whenever a new searcher is being
         prepared but there is no current registered searcher to handle
         requests or to gain autowarming data from.

      -->
    <!-- QuerySenderListener takes an array of NamedList and executes a
         local query request for each NamedList in sequence.
      -->
    <listener event="newSearcher" class="solr.QuerySenderListener">

```
        <lst>
          <str name="q">static firstSearcher warming in solrconfig.xml</str>
        </lst>
        -->
      </arr>
    </listener>

    <!-- Use Cold Searcher

         If a search request comes in and there is no current
         registered searcher, then immediately register the still
         warming searcher and use it.  If "false" then all requests
         will block until the first searcher is done warming.
      -->
    <useColdSearcher>false</useColdSearcher>
    <!-- Slow Query Request Logging

         Any queries that take longer than the specified threshold
         will be logged as "slow" queries.
         To disable slow request logging for this Solr config,
         set the value to -1
      -->
    <slowQueryThresholdMillis>5000</slowQueryThresholdMillis>

  </query>

  <!-- Request Dispatcher

       This section contains instructions for how the SolrDispatchFilter
       should behave when processing requests for this SolrCore.

    -->
  <requestDispatcher>
    <!-- Request Parsing

         These settings indicate how Solr Requests may be parsed, and
         what restrictions may be placed on the ContentStreams from
         those requests
         enableRemoteStreaming - enables use of the stream.file
         and stream.url parameters for specifying remote streams.

         multipartUploadLimitInKB - specifies the max size (in KiB) of
         Multipart File Uploads that Solr will allow in a Request.

         formdataUploadLimitInKB - specifies the max size (in KiB) of
         form data (application/x-www-form-urlencoded) sent via
         POST. You can use POST to pass request parameters not
         fitting into the URL.

         addHttpRequestToContext - if set to true, it will instruct
         the requestParsers to include the original HttpServletRequest
         object in the context map of the SolrQueryRequest under the
         key "httpRequest". It will not be used by any of the existing
         Solr components, but may be useful when developing custom
         plugins.
         *** WARNING ***
         Before enabling remote streaming, you should make sure your
         system has authentication enabled.

      -->
    <requestParsers enableRemoteStreaming="true"
                    multipartUploadLimitInKB="2048000"
                    formdataUploadLimitInKB="2048"
```

```
                    addHttpRequestToContext="true"/>

  <!-- HTTP Caching

       Set HTTP caching related parameters (for proxy caches and clients).

       The options below instruct Solr not to output any HTTP Caching
       related headers
    -->
  <httpCaching never304="true" />
  <!-- If you include a <cacheControl> directive, it will be used to
       generate a Cache-Control header (as well as an Expires header
       if the value contains "max-age=")
       By default, no Cache-Control header is generated.
       You can use the <cacheControl> option even if you have set
       never304="true"
    -->
  <!--
     <httpCaching never304="true" >
       <cacheControl>max-age=30, public</cacheControl>
     </httpCaching>
    -->
  <!-- To enable Solr to respond with automatically generated HTTP
       Caching headers, and to response to Cache Validation requests
       correctly, set the value of never304="false"

       This will cause Solr to generate Last-Modified and ETag
       headers based on the properties of the Index.

       The following options can also be specified to affect the
       values of these headers...

       lastModFrom - the default value is "openTime" which means the
       Last-Modified value (and validation against If-Modified-Since
       requests) will all be relative to when the current Searcher
       was opened.  You can change it to lastModFrom="dirLastMod" if
       you want the value to exactly correspond to when the physical
       index was last modified.

       etagSeed="..." is an option you can change to force the ETag
       header (and validation against If-None-Match requests) to be
       different even if the index has not changed (ie: when making
       significant changes to your config file)
       (lastModifiedFrom and etagSeed are both ignored if you use
       the never304="true" option)
    -->
  <!--
     <httpCaching lastModifiedFrom="openTime"
                  etagSeed="Solr">
       <cacheControl>max-age=30, public</cacheControl>
     </httpCaching>
    -->
</requestDispatcher>

<!-- Request Handlers

     http://wiki.apache.org/solr/SolrRequestHandler

     Incoming queries will be dispatched to a specific handler by name
     based on the path specified in the request.

     If a Request Handler is declared with startup="lazy", then it will
     not be initialized until the first request that uses it.
```

```
    -->
  <!-- SearchHandler
       http://wiki.apache.org/solr/SearchHandler

       For processing Search Queries, the primary Request Handler
       provided with Solr is "SearchHandler" It delegates to a sequent
       of SearchComponents (see below) and supports distributed
       queries across multiple shards
    -->

<requestHandler name="/get" class="solr.RealTimeGetHandler">
  <lst name="defaults">

      </arr>
</requestHandler>

 <requestHandler name="/select" class="solr.SearchHandler">
    <!-- default values for query parameters can be specified, these
         will be overridden by parameters in the request
      -->
    <lst name="defaults">
      <str name="echoParams">explicit</str>
      <int name="rows">10</int>
      <!-- Default search field
         <str name="df">text</str>
        -->
      <!-- Change from JSON to XML format (the default prior to Solr 7.0)
         <str name="wt">xml</str>
        -->
    </lst>
    <!-- In addition to defaults, "appends" params can be specified
         to identify values which should be appended to the list of
         multi-val params from the query (or the existing "defaults").
      -->
    <!-- In this example, the param "fq=instock:true" would be appended to
         any query time fq params the user may specify, as a mechanism for
         partitioning the index, independent of any user selected filtering
         that may also be desired (perhaps as a result of faceted searching
).

         NOTE: there is *absolutely* nothing a client can do to prevent thes
e
         "appends" values from being used, so don't use this mechanism
         unless you are sure you always want it.
      -->
    <!--
       <lst name="appends">
         <str name="fq">inStock:true</str>
       </lst>
      -->
    <!-- "invariants" are a way of letting the Solr maintainer lock down
         the options available to Solr clients.  Any params values
         specified here are used regardless of what values may be specified
         in either the query, the "defaults", or the "appends" params.

         In this example, the facet.field and facet.query params would
```

```
         be fixed, limiting the facets clients can use.  Faceting is
         not turned on by default - but if the client does specify
         facet=true in the request, these are the only facets they
         will be able to see counts for; regardless of what other
         facet.field or facet.query params they may specify.

         NOTE: there is *absolutely* nothing a client can do to prevent th
ese
         "invariants" values from being used, so don't use this mechanism
         unless you are sure you always want it.
      -->
    <!--
       <lst name="invariants">
         <str name="facet.field">cat</str>
         <str name="facet.field">manu_exact</str>
         <str name="facet.query">price:[* TO 500]</str>
         <str name="facet.query">price:[500 TO *]</str>
       </lst>
      -->
    <!-- If the default list of SearchComponents is not desired, that
         list can either be overridden completely, or components can be
         prepended or appended to the default list.  (see below)
      -->
    <!--
       <arr name="components">
         <str>nameOfCustomComponent1</str>
         <str>nameOfCustomComponent2</str>
       </arr>
      -->
      <arr name="first-components">
        <str>queryDocAuthorization</str>
      </arr>
  </requestHandler>

  <!-- A request handler that returns indented JSON by default -->
  <requestHandler name="/query" class="solr.SearchHandler">
    <lst name="defaults">
      <str name="echoParams">explicit</str>
      <str name="wt">json</str>
      <str name="indent">true</str>
    </lst>
    <arr name="first-components">
       <str>queryDocAuthorization</str>
    </arr>
  </requestHandler>

      <str name="df">_text_</str>
    </lst>
  </initParams>

  <!-- Search Components

       Search components are registered to SolrCore and used by
       instances of SearchHandler (which can access them by name)

       By default, the following components are available:

       <searchComponent name="query"     class="solr.QueryComponent" />
       <searchComponent name="facet"     class="solr.FacetComponent" />
       <searchComponent name="mlt"       class="solr.MoreLikeThisComponen
t" />
       <searchComponent name="highlight" class="solr.HighlightComponent" />
```

```
       <searchComponent name="stats"     class="solr.StatsComponent" />
       <searchComponent name="debug"     class="solr.DebugComponent" />

       Default configuration in a requestHandler would look like:

       <arr name="components">
         <str>query</str>
         <str>facet</str>
         <str>mlt</str>
         <str>highlight</str>
         <str>stats</str>
         <str>debug</str>
       </arr>

       If you register a searchComponent to one of the standard names,
       that will be used instead of the default.

       To insert components before or after the 'standard' components, use:

       <arr name="first-components">
         <str>myFirstComponentName</str>
       </arr>
       <arr name="last-components">
         <str>myLastComponentName</str>
       </arr>

       NOTE: The component registered with the name "debug" will
       always be executed after the "last-components"

     -->

  <searchComponent name="queryDocAuthorization" class="org.apache.ranger.a
uthorization.solr.authorizer.RangerSolrAuthorizer">
    <str name="enabled">true</str>
    <!-- The field which contains the role or list of roles which are allow
ed to query a particular document -->
    <str name="rangerAuthField">ranger_auth</str>
